Middleware Systems for Efficient and Robust Distributed Machine Learning

Item Type Conference Paper

Author R.A. Bhope

Abstract Distributed machine learning faces fundamental challenges arising from heterogeneous data, shifting client populations, and volatile inference workloads. This dissertation advances the thesis that middleware - not the models themselves - must serve as an active, adaptive decision layer that unifies training-time and inference-time robustness. On the training side, FLIPS performs privacy-preserving participant selection via label-distribution clustering within TEEs, improving fairness and convergence under non-IID data, while ShiftEx detects covariate and label shifts in streaming environments and dynamically creates or reuses experts to accelerate adaptation with minimal retraining. On the inference side, OptiSeq improves the reliability of LLM-based API sequencing by selecting example orderings using inference-time log-probability reasoning, and VOILA formulates multimodal fidelity selection as a value-of-information optimization,

achieving large cost reductions with calibrated accuracy guarantees. Together, these systems establish adaptive middleware as a unifying approach for improving efficiency, robustness, and accuracy across modern distributed ML deployments. © 2025 Copyright held by the owner/author(s).

Migraine and white matter hyperintensities: Protocol for a systematic review and meta-analysis

Item Type Journal Article

Abstract White matter hyperintensities (WMHs) are common MRI findings and established markers of cerebral small-vessel disease associated with stroke, cognitive decline, and vascular risk factors. Several studies have suggested that individuals with migraine, particularly migraine with aura (MA), may have an increased burden of WMHs compared with individuals without migraine. Early population-based studies and meta-analyses reported a higher prevalence of WMHs in migraine, whereas more recent large neuroimaging cohorts have reported conflicting findings or no association. Differences in study design, migraine ascertainment, MRI acquisition parameters, WMH quantification methods, and adjustment for vascular risk factors complicate interpretation of the existing literature. An updated systematic review focusing on methodologically comparable population-based cohorts is therefore warranted. The primary objective of this systematic review and meta-analysis is to determine whether adults with migraine have a higher prevalence or burden of WMHs on MRI than non-migraine controls. Secondary objectives include evaluating associations according to migraine subtype (MA vs. migraine without aura and episodic vs. chronic migraine), sex, WMH location, age, and MRI acquisition or WMH quantification methods, as well as examining longitudinal WMH progression where available. We will include population-based cross-sectional or longitudinal cohort studies of adults undergoing brain MRI with sequences suitable for WMH detection. Migraine exposure may be defined using International Classification of Headache Disorders criteria, structured interviews, validated questionnaires, physician diagnosis, or ICD codes. Controls must originate from the same source population. Searches will be conducted in PubMed/MEDLINE, EMBASE, Web of Science, and Scopus. Study selection, data extraction, and risk-of-bias assessment will be performed independently by two reviewers using Covidence, and risk of bias will be evaluated using the ROBINS-E tool. Because WMH burden is reported using heterogeneous metrics across studies, the primary synthesis will use a precision-weighted direction-of-effect approach, in which each study contributes the direction of the association, weighted by statistical precision. Where sufficiently comparable outcomes are available, random-effects meta-analysis will be performed. Sensitivity analyses will explore the influence of diagnostic criteria, MRI field strength, and confounder adjustment. This review will provide an updated and methodologically rigorous synthesis of the evidence on the association between migraine and WMHs. © The Author(s) 2026. Mind the class weight bias: Weighted maximum mean discrepancy for unsupervised domain adaptation

Item Type Conference Paper

Author H. Yan

Author Y. Ding

Author P. Li

Author Q. Wang

Author Y. Xu

Author W. Zuo

Abstract In domain adaptation, maximum mean discrepancy (MMD) has been widely adopted as a discrepancy metric between the distributions of source and target domains. However, existing MMD-based domain adaptation methods generally ignore the changes of class prior distributions, i.e., class weight bias across domains. This remains an open problem but ubiquitous for domain adaptation, which can be caused by changes in sample selection criteria and application scenarios. We show that MMD cannot account for class weight bias and results in

degraded domain adaptation performance. To address this issue, a weighted MMD model is proposed in this paper. Specifically, we introduce class-specific auxiliary weights into the original MMD for exploiting the class prior probability on source and target domains, whose challenge lies in the fact that the class label in target domain is unavailable. To account for it, our proposed weighted MMD model is defined by introducing an auxiliary weight for each class in the source domain, and a classification EM algorithm is suggested by alternating between assigning the pseudo-labels, estimating auxiliary weights and updating model parameters. Extensive experiments demonstrate the superiority of our weighted MMD over conventional MMD for domain adaptation. © 2017 IEEE.

Abstract Real-world agricultural distributions often suffer from severe class imbalance, typically following a long-tailed distribution. Labeled datasets for crop-type classification are inherently scarce and remain costly to obtain. When working with such limited data, training sets are frequently constructed to be artificially balanced-in particular in the case of few-shot learning-failing to reflect real-world conditions. This mismatch induces a shift between training and test label distributions, degrading real-world generalization. To address this, we propose Dirichlet Prior Augmentation (DirPA), a novel method that simulates an unknown label distribution skew of the target domain proactively during model training. Specifically, we model the real-world distribution as Dirichlet-distributed random variables, effectively performing a prior augmentation during few-shot learning. Our experiments show that DirPA successfully shifts the decision boundary and stabilizes the training process by acting as a dynamic feature regularizer. © Copyright: 2026 Joana Reuss et al.

Minimax classifiers based on neural networks

Item Type Journal Article**Author** R. Alaiz-Rodríguez**Author** A. Guerrero-Curieses**Author** J. Cid-Sueiro

Abstract The problem of designing a classifier when prior probabilities are not known or are not representative of the underlying data distribution is discussed in this paper. Traditional learning approaches based on the assumption that class priors are stationary lead to sub-optimal solutions if there is a mismatch between training and future (real) priors. To protect against this uncertainty, a minimax approach may be desirable. We address the problem of designing a neural-based minimax classifier and propose two different algorithms: a learning rate scaling algorithm and a gradient-based algorithm. Experimental results show that both succeed in finding the minimax solution and it is also pointed out the differences between common approaches to cope with this uncertainty in priors and the minimax classifier. © 2004 Pattern Recognition Society. Minimax confidence intervals for the Sliced Wasserstein distance***Item Type** Journal Article**Author** T. Manole**Author** S. Balakrishnan**Author** L. Wasserman

Abstract Motivated by the growing popularity of variants of the Wasserstein distance in statistics and machine learning, we study statistical inference for the Sliced Wasserstein distance—an easily computable variant of the Wasserstein distance. Specifically, we construct confidence intervals for the Sliced Wasserstein distance which have finite-sample validity under no assumptions or under mild moment assumptions. These intervals are adaptive in length to the regularity of the underlying distributions. We also bound the minimax risk of estimating the Sliced Wasserstein distance, and as a consequence establish that the lengths of our proposed confidence intervals are minimax optimal over appropriate distribution classes. To motivate the choice of these classes, we also study minimax rates of estimating a distribution under the Sliced Wasserstein distance. These theoretical findings are complemented with a simulation study demonstrating the deficiencies of the classical bootstrap, and the advantages of our proposed methods. We also show strong correspondences between our theoretical predictions and the adaptivity of our confidence interval lengths in simulations. We conclude by demonstrating the use of our confidence intervals in the setting of simulator-based likelihood-free inference. In this setting, contrasting popular approximate Bayesian computation methods, we develop uncertainty quantification methods with rigorous frequentist coverage guarantees. © 2022, Institute of Mathematical Statistics. Minimax optimal approaches to the label shift problem in non-parametric settings

Item Type Journal Article

Author S. Maity

Author Y. Sun

Author M. Banerjee

Abstract We study the minimax rates of the label shift problem in non-parametric classification. In addition to the unsupervised setting in which the learner only has access to unlabeled examples from the target domain, we also consider the setting in which a small number of labeled examples from the target domain is available to the learner. Our study reveals a difference in the difficulty of the label shift problem in the two settings, and we attribute this difference to the availability of data from the target domain to estimate the class conditional distributions in the latter setting. We also show that a class proportion estimation approach is minimax rate-optimal in the unsupervised setting. ©2022 Subha Maity, Yuekai Sun, and Moulinath Banerjee.

- Abstract** Most supervised learning algorithms are based on the assumption that the training data set reflects the underlying statistical model of the real data. However, this stationarity assumption is not always satisfied in practice: quite frequently, class prior probabilities are not in accordance with the class proportions in the training data set. The minimax approach is based on selecting the classifier that minimize the error probability under the worst case conditions. We propose a two-step learning algorithm to train a neural network in order to estimate the minimax classifier that is robust to changes in the class priors. During the first step, posterior probabilities based on training data priors are estimated. During the second step, class priors are modified in order to minimize a cost function that is asymptotically equivalent to the worst-case error rate. This procedure is illustrated on a softmax-based neural network. Several experimental results show the advantages of the proposed method with respect to other approaches. © 2002 IEEE.

Minimising quantifier variance under prior probability shift

Item Type Conference Paper

Author D. Tasche

Editor Cong G.

Editor Ramanath M.

Abstract For the binary prevalence quantification problem under prior probability shift, we determine the asymptotic variance of the maximum likelihood estimator. We find that it is a function of the Brier score for the regression of the class label on the features under the test data set distribution. This observation suggests that optimising the accuracy of a base classifier, as measured by the Brier score, on the training data set helps to reduce the variance of the related quantifier on the test data set. Therefore, we also point out training criteria for the base classifier that imply optimisation of both of the Brier scores on the training and the test data sets. © 2021 Copyright for this paper by its authors. Minimizing error in measurement of error: A proposed method for calculation of error in a two-dimensional motor task

Item Type Journal Article**Author** J. Kim**Author** S. Chung**Author** L.K. Tennant**Author** R.N. Singer**Author** C.M. Janelle

Abstract Traditional one-dimensional error scores are still consistently used in research on motor learning to quantify two-dimensional error; however, the inherent differences in two-dimensional tasks rejider that application inappropriate and often misleading. Consequently, the purpose of this paper was to propose a novel method of presenting errors, which more precisely represents the accuracy, direction, and variability of error in two-dimensional settings. Although closely related to several alternatives for representing errors, the methodology used and the results obtained provide a more accurate procedure for pinpointing critical trends in what have been commonly referred to as AE (absolute error), VE (variable error), CE (constant error), and E (total variability). The proposed measurements of AVTZ (adjusted variable error), DE (directional error), TSE (total spread of error), and RE (radial error) provide composite error scores carrying a variety of information about performance on two-dimensional tasks. Formulas and examples are provided to facilitate computation and enhance understanding of the proposed scores.

Minimizing Estimated Risks on Unlabeled Data: A New Formulation for Semi-Supervised Medical Image Segmentation

Item Type Journal Article

Author F. Wu

Author X. Zhuang

Abstract Supervised segmentation can be costly, particularly in applications of biomedical image analysis where large scale manual annotations from experts are generally too expensive to be available. Semi-supervised segmentation, able to learn from both the labeled and unlabeled images, could be an efficient and effective alternative for such scenarios. In this work, we propose a new formulation based on risk minimization, which makes full use of the unlabeled images. Different from most of the existing approaches which solely explicitly guarantee the minimization of prediction risks from the labeled training images, the new formulation also considers the risks on unlabeled images. Particularly, this is achieved via an unbiased estimator, based on which we develop a general framework for semi-supervised image segmentation. We validate this framework on three medical image segmentation tasks, namely cardiac segmentation on ACDC2017, optic cup and disc segmentation on REFUGE dataset and 3D whole heart segmentation on MM-WHS dataset. Results show that the proposed estimator is effective, and the segmentation method achieves superior performance and demonstrates great potential compared to the other state-of-the-art approaches. Our code and data will be released via <https://zmiclalab.github.io/projects.html>, once the manuscript is accepted for publication. © 1979-2012 IEEE.

Editor Levine S.

Abstract Recalibrating probabilistic classifiers is vital for enhancing the reliability and accuracy of predictive models. Despite the development of numerous recalibration algorithms, there is still a lack of a comprehensive theory that integrates calibration and sharpness (which is essential for maintaining predictive power). In this paper, we introduce the concept of minimum-risk recalibration within the framework of mean-squared-error (MSE) decomposition, offering a principled approach for evaluating and recalibrating probabilistic classifiers. Using this framework, we analyze the uniform-mass binning (UMB) recalibration method and establish a finite-sample risk upper bound of order $\tilde{O}(B/n + 1/B^2)$ where B is the number of bins and n is the sample size. By balancing calibration and sharpness, we further determine that the optimal number of bins for UMB scales with $n^{1/3}$, resulting in a risk bound of approximately $O(n^{-2/3})$. Additionally, we tackle the challenge of label shift by proposing a two-stage approach that adjusts the recalibration function using limited labeled data from the target domain. Our results show that transferring a calibrated classifier requires significantly fewer target samples compared to recalibrating from scratch. We validate our theoretical findings through numerical simulations, which confirm the tightness of the proposed bounds, the optimal number of bins, and the effectiveness of label shift adaptation. © 2023 Neural information processing systems foundation. Minor mining, major influence: Economic implications and policy challenges of artisanal gold mining

Item Type Journal Article

Author M. Yu

Author Y. Wang

Author M. Umair

Abstract This study presents an in-depth analysis of the economic policies and implications surrounding artisanal gold mining, reframing the discussion from geographical specifics to a broader policy and economic context. Utilizing advanced geospatial data from the Landsat image collection through “Google Earth Engine,” the research evaluates the economic impact and policy challenges posed by artisanal gold mining over a period from 2011 to 2021. The approach combines change detection methodologies with machine learning to quantify the economic repercussions of land cover changes due to mining. The analysis reveals significant economic transformations, with an average of 2700 ha of land affected annually, culminating in around 48,000 ha over the decade, highlighting a critical period from 2013 to 2020. Importantly, the study identifies policy gaps, especially in the management of protected areas where approximately 800 ha of mining occurred. The findings underscore the urgent need for policy interventions to mitigate the adverse economic and environmental impacts of unregulated mining. The study contributes to a broader understanding of the economic ramifications of artisanal mining and serves as a call to action for policymakers to address the challenges of sustainable mining practices and economic development. © 2024

Mitigating Diagnostic Errors in Lung Cancer Classification: A Multi-Eyes Principle to Uncertainty Quantification

Item Type Journal Article

Author R. Zahari

Author J. Cox

Author B. Obara

Abstract In radiology, particularly in lung cancer diagnosis, diagnostic errors and cognitive biases pose substantial challenges. These issues, including perceptual errors, interpretive mistakes, and cognitive biases such as anchoring and premature closure, are often unnoticed by experienced radiologists. To address these challenges, we propose the Multi-Eyes principle approach, which utilises multiple deep learning models to reduce bias and potentially improve diagnostic accuracy. Inspired by the Four-Eyes principle in business and cybersecurity, this methodology employs various 3D and 2D (for validation) deep learning architectures and three uncertainty quantification techniques: Monte Carlo Dropout, Deep Ensemble, and Ensemble Monte Carlo Dropout. Each model functions as an independent reviewer, similar to blind reviews. With entropy selected as the uncertainty measurement, it is averaged, followed by ensemble averaging of predictions. The effectiveness of this approach was demonstrated using the LIDC-IDRI dataset for lung cancer classification. Statistical analysis of the uncertainty's distribution reveals that with more models, uncertainty in incorrect predictions becomes more peaked and left skewed, indicating consensus on uncertainty levels. This results in accuracy and F1 score improvements, even with the best performing model, addressing overconfidence in single-model systems. These findings highlight the potential of the Multi-Eyes principle to significantly improve diagnostic performance in computer-aided diagnostic systems. Future research may explore different uncertainty quantification methods and feedback mechanisms for further advancement. © 2013 IEEE.

Mitigating Overfitting in Supervised Classification from Two Unlabeled Datasets: A Consistent Risk Correction Approach

Item Type Conference Paper

Author N. Lu

Author T. Zhang

Author G. Niu

Author M. Sugiyama

Editor Chiappa S.

Editor Calandra R.

Abstract The recently proposed unlabeled-unlabeled (UU) classification method allows us to train a binary classifier only from two unlabeled datasets with different class priors. Since this method is based on the empirical risk minimization, it works as if it is a supervised classification method, compatible with any model and optimizer. However, this method sometimes suffers from severe overfitting, which we would like to prevent in this paper. Our empirical finding in applying the original UU method is that overfitting often co-occurs with the empirical risk going negative, which is not legitimate. Therefore, we propose to wrap the terms

that cause a negative empirical risk by certain correction functions. Then, we prove the consistency of the corrected risk estimator and derive an estimation error bound for the corrected risk minimizer. Experiments show that our proposal can successfully mitigate overfitting of the UU method and significantly improve the classification accuracy. Copyright © 2020 by the author(s)

Mitigating Source Label Dependency in Time-Series Domain Adaptation under Label Shifts

Item Type Conference Paper

Author J. Na

Author Y. Nam

Author J. Kang

Author J.-G. Lee

Abstract Time-series unsupervised domain adaptation (TS-UDA) is essential in fields such as healthcare and manufacturing, where data often consists of distinct entities, such as individual patients or machinery. This heterogeneity leads to

discrepancies not only in feature distributions but also in label distributions, posing a significant challenge for domain adaptation. However, prior studies have mostly focused on alleviating covariate shifts, resulting in predicted target labels that are often biased toward the source domain's label distribution. To address this issue, we propose Time-series domain Adaptation for mitigating Label Shifts (TA4LS), a novel label refinement approach. TA4LS leverages the consistency between predicted labels and clustering information obtained from the unique characteristics that differentiate each label in the target domain. Furthermore, our approach as a plug-in module achieves performance improvements across diverse existing unsupervised domain adaptation methods, particularly in scenarios with significant discrepancies between source and target label distributions. In experiments on four benchmark datasets with label shifts, TA4LS demonstrates superior performance across six unsupervised domain adaptation methods and six label shift handling modules. © 2025 Association for Computing Machinery. Abstract Prompt-based classifiers are an attractive approach for zero-shot classification. However, the precise choice of the prompt template and label words can largely influence performance, with semantically equivalent settings often showing notable performance difference. This discrepancy can be partly attributed to word biases, where the classifier may be biased towards classes. To address this problem, it is possible to optimise classification thresholds on a labelled data set, however, this mitigates some of the advantages of prompt-based classifiers. This paper instead approaches this problem by examining the expected marginal probabilities of the classes. Here, probabilities are reweighted to have a uniform prior over classes, in an unsupervised fashion. Further, we draw a theoretical connection between the class priors and the language models' word prior, and offer the ability to set a threshold in a zero-resource fashion. We show that matching class priors correlates strongly with the oracle upper bound performance and demonstrate large consistent performance gains for prompt settings over a range of NLP tasks. © 2023 Asian Federation of Natural Language Processing.

Mitotic HEp-2 cells recognition under class skew

Item Type Conference Paper

Author G. Percannella

Author P. Soda

Author M. Vento

Abstract Indirect immunofluorescence (IIF) is the recommended method to diagnose the presence of antinuclear autoantibodies in patient serum. A main step of the diagnostic procedure requires to detect mitotic cells in the well under examination. However, such cells rarely occur in comparison to other cells and, hence, traditional recognition algorithms fail in this task since they cannot cope with large differences between the number of samples in each class, resulting in a low predictive accuracy over the minority class. In this paper we present a system for mitotic cells recognition based on multiobjective optimisation, which is able to handle their low a priori probability. It chooses between the output of a classifier trained on the original skewed distribution and the output of a classifier trained according to a learning method addressing the course of imbalanced data. This choice is driven by a parameter whose value maximises, on a validation set, two objective functions, i.e. the global accuracy and the accuracies for each class. The approach has been evaluated on an annotated dataset of mitotic cells and successfully compared to five learning methods applying four different

classification paradigms. © 2011 Springer-Verlag.

Mitral regurgitation severity analysis based on features and optimal HE (OHE) with quantification using PISA method

Item Type Journal Article

Author P.A. Khayum

Author R.P.S. Babu

Abstract Heart disease is the foremost reason for death and also the main source of incapability in the developed nations. Mitral regurgitation (MR) is a typical heart disease that does not bring about manifestations until its end position. In view of the hidden etiologies of heart distress, functional MR can be partitioned into two subgroups, ischemic and no ischemic MR. A procedure is progressed for jet area separation and quantification in MR evaluation in arithmetical expressions. Thus, a strategy that depends on

echocardiography recordings, image processing methods, and artificial intelligence could be useful for clinicians, particularly in marginal cases. In this research paper, MR segmentation is analyzed by the optimal histogram equalization (OHE) system used to segment the jet area. For a better execution of the work, threshold in HE was improved with the help of the krill herd optimization (KHO) strategy. With the MR quantification procedure, this segmented jet area was supported by the proximal isovelocity surface area (PISA); in this procedure, a few parameters in the segmentation were evaluated. From the results, this proposed methodology accomplishes better accuracy in the segmented and quantification method in contrast with the existing examination. © 2019 De Gruyter. All rights reserved.

Mixed Mode Latent Class Analysis: An Examination of Fit Index Performance for Classification

Item Type Journal Article

Author G.B. Morgan

Abstract This Monte Carlo study examines the performance of fit indices commonly used by applied researchers interested in finite mixture modeling for the purposes of classification. Conditions for the simulation study were selected to reflect conditions found in applied educational and psychological research. The factors included in the investigation were metric level of indicators, sample size, and class prevalence. All models contained a combination of categorical and continuous indicators. All categorical indicators were dichotomous, and continuous indicators were normally distributed. The fit indices examined were Akaike's information criterion, Bayesian information criterion (BIC), sample size-adjusted Bayesian information criterion (SSBIC), integrated classification likelihood criterion with Bayesian-type approximation, and Lo–Mendell–Rubin likelihood ratio test. Overall, SSBIC tended to identify the correct solution with higher frequency than other indices. BIC tended to identify the correct solution with higher frequency than the other indices in models with more continuous than categorical indicators, or when rare classes were absent. © Taylor & Francis Group, LLC.

Mixed-dual-head Meets Box Priors: A Robust Framework for Semi-supervised Segmentation

Item Type Conference Paper

Author C. Chen

Author T. Liu

Author W. Tan

Author S. Pu

Abstract As it is costly to densely annotate large scale datasets for supervised semantic segmentation, extensive semi-supervised methods have been proposed. However, the accuracy, stability and flexibility of existing methods are still far from satisfactory. In this paper, we propose an effective and flexible framework for semi-supervised semantic segmentation using a small set of fully labeled images and a set of weakly labeled images with bounding box labels. In our framework, position and class priors are designed to guide the annotation network to predict accurate pseudo masks for weakly labeled images, which are used to train the segmentation network. We also propose a mixed-dual-head training method to reduce the interference of label noise while enabling the training process more stable. Experiments on PASCAL VOC 2012 show that our method achieves state-of-the-art performance and can achieve competitive results even with very few fully labeled images. Furthermore, the performance can be further boosted with extra weakly labeled images from COCO dataset. © 2022 IEEE.

Mixture-of-Experts for Open Set Domain Adaptation: A Dual-Space Detection Approach

Item Type Journal Article

Author Z. Du

Author J. An

Author Y. Tu

Author J. Hong

Author D. Wu

Abstract Open set domain adaptation (OSDA) copes with the distribution and label shifts between the source and target domains simultaneously, performing accurate classification for known classes while identifying unknown class samples in the target domain. Most existing OSDA approaches, depending on the final image feature space of deep models, require manually-tuned thresholds, and may easily misclassify unknown samples as known classes. Mixture-of-experts (MoE) could be a remedy. Within an MoE, different experts handle distinct input features, producing unique expert routing patterns for various classes in a routing feature space. As a result, unknown class samples may display different expert routing patterns to known classes. This article proposes dual-space detection, which exploits the inconsistencies between the image feature space and the routing feature space to detect unknown class samples without any threshold. A graph router is further introduced to better make use of the spatial information among the image patches. Experiments on three datasets validated the effectiveness and superiority of our approach. © 2020 IEEE.

MobileNetV3-DETR with locality-biased decoding for chip-leg defects on embedded AOI

Item Type Journal Article

Author Z. Zhang

Author H. Liu

Author B. Huang

Abstract We present a scene-specific MobileNetV3-DETR for chip-leg defect inspection, where targets are tiny, dense, and arranged on a regular lattice. Instead of stacking generic tricks, we formalize three complementary mechanisms: (A1) a task-aligned FPN pruning criterion that selects the minimal pyramid levels {P3–P5} to match the empirical defect-size distribution; (A2) a lattice-aware relative positional encoding that biases attention toward physically plausible row/column offsets; and (A3) a defect-prior adaptive Top-K sparse attention that allocates the decoder’s attention budget by local response quantiles with a device-aware cap $K_{\max}$. In training, a defect-aware assignment (D-AA) re-weights the Hungarian classification term by smoothed class priors, improving recall of rare, safety-critical defects without changing the inference graph. Under a unified embedded protocol on Jetson Nano (TensorRT FP16, 512×512 , batch = 1), the model uses ~ 7.2 M parameters and ~ 29.9 GFLOPs, reaches 89.5% mAP@50 and an average of 55.25% mAP@[0.5:0.95], and delivers ≈ 60 ms per image. Ablations demonstrate independent gains from A1–A3, while confusion-matrix analysis confirms reduced errors on the hardest pairs (e.g., bent_leg vs. damaged_leg; dirty vs. scratches), indicating an improved accuracy–latency balance for inline AOI deployment. © The Author(s) 2026.

Model and score adaptation for biometric systems: Coping with device interoperability and changing acquisition conditions

Item Type Conference Paper

Author N. Poh

Author J. Kittler

Author S. Marcel

Author D. Matrouf

Author J.-F. Bonastre

Abstract The performance of biometric systems can be significantly affected by changes in signal quality. In this paper, two types of changes are considered: change in acquisition environment and in sensing devices. We investigated three solutions: (i) model-level adaptation, (ii) score-level adaptation (normalisation), and (iii) the combination of the two, called "compound" adaptation. In order to cope with the above changing conditions, the model-level adaptation attempts to update the parameters of the expert systems (classifiers). This approach requires the authenticity of the candidate samples used for adaptation be known (corresponding to supervised adaptation), or can be estimated (unsupervised adaptation). In comparison, the score-level adaptation merely involves postprocessing the expert output, with the objective of rendering the associated decision threshold to be dependent only on the class priors despite the changing acquisition conditions. Since the above adaptation strategies treat the underlying biometric experts/classifiers as a black-box, they can be applied to any unimodal or multimodal biometric system, thus facilitating system-level integration and performance optimisation. Our contributions are: (i) proposal of compound adaptation; (ii) investigation and comparison of two different quality-dependent

score normalisation strategies; and, (iii) empirical comparison of the merit of the above three solutions on the BANCA face (video) and speech database. © 2010 IEEE.

Model Uncertainty and Correctability for Directed Graphical Models*

Item Type Journal Article

Author P. Birmpa

Author J. Feng

Author M.A. Katsoulakis

Author L. Rey-Bellet

Abstract Probabilistic graphical models are a fundamental tool in probabilistic modeling, machine learning, and artificial intelligence. They allow us to integrate in a natural way expert knowledge, physical modeling, heterogeneous and correlated data, and quantities of interest. For exactly this reason, multiple sources of model uncertainty are inherent within the modular structure of the graphical model. In this paper we develop information-theoretic, robust uncertainty quantification methods and nonparametric stress tests for directed graphical models to assess the effect and the

propagation through the graph of multisourced model uncertainties to quantities of interest. These methods allow us to rank the different sources of uncertainty and correct the graphical model by targeting its most impactful components with respect to the quantities of interest. Thus, from a machine learning perspective, we provide a mathematically rigorous approach to correctability that guarantees a systematic selection for improvement of components of a graphical model while controlling potential new errors created in the process in other parts of the model. We demonstrate our methods in two physicochemical examples, namely, quantum scale-informed chemical kinetics and materials screening to improve the efficiency of fuel cells. © 2022 Society for Industrial and Applied Mathematics and American Statistical Association.

Modeling and characterizing software vulnerabilities

Item Type Journal Article

Author N. Bhatt**Author** A. Anand**Author** V.S.S. Yadavalli**Author** V. Kumar

Abstract With the association of software security assurance in the development of code based systems; software developers are relying on the Vulnerability discovery models to mitigate the breaches by estimating the total number of vulnerabilities, before they're exploited by the intruders. Vulnerability Discovery Models (VDMs) provide the quantitative classification of the flaws that exists in a software that will be discovered after a software is released. In this paper, we develop a vulnerability discovery model that accumulate the vulnerabilities due to the influence of previously discovered vulnerabilities. We further evaluate the proportion of previously discovered vulnerabilities along with the fraction additional vulnerabilities detected. The quantification methodology presented in this article has been accompanied with an empirical illustration on popular operating systems' vulnerability data. © 2017, International Journal of Mathematical, Engineering and Management Sciences.

Modeling Groundwater Resources in Data-Scarce Regions for Sustainable Management: Methodologies and Limits

Item Type Journal Article

Author I. Borzi

Abstract Groundwater modeling in data-scarce regions faces significant challenges due to the lack of comprehensive, high-quality data, impacting model accuracy. This systematic review of Scopus-indexed papers identifies various approaches to address these challenges, including coupled hydrological-groundwater models, machine learning techniques, distributed hydrological models, water balance models, 3D groundwater flow modeling, geostatistical techniques, remote sensing-based approaches, isotope-based methods, global model downscaling, and integrated modeling approaches. Each methodology offers unique advantages for groundwater assessment and management in data-poor environments, often combining multiple data sources and modeling techniques to overcome limitations. However, these approaches face common challenges related to data quality, scale transferability, and the representation of complex hydrogeological processes. This review emphasizes the importance of adapting methodologies to specific regional contexts and data availability. It underscores the value of combining multiple data sources and modeling techniques to provide robust estimates for sustainable groundwater management. The choice of method ultimately depends on the specific objectives, scale of the study, and available data in the region of interest. Future research should focus on improving the integration of diverse data sources, enhancing the representation of complex hydrogeological processes in simplified models, and developing robust uncertainty quantification methods tailored for data-scarce conditions. © 2025 by the author.

Author L. Gudmundsson

Abstract Deep learning enables precise environmental predictions across spatial and temporal scales. However, reliable uncertainty estimation with generative capabilities remains crucial for actionable forecasting and simulation, yet robust quantification methods remain challenging. Recently, engression, a generative approach for model-agnostic uncertainty quantification, has been proposed. We evaluate its feasibility for environmental time-series modeling, specifically applying it to rainfall-runoff prediction using long short-term memory (LSTM) networks. As a benchmark, we use quantile regression, a generalization of the mean absolute error. In our analysis, we focus on the quality of the uncertainty estimates and realism of generated sequences, while including a comparison to point-prediction performance as a sanity check. Our results show that LSTM-engression is an effective and easy-to-use method for generative modeling, outperforming quantile regression in uncertainty quantification. Qualitative analysis of the generated time series indicates high dynamic fidelity. These findings highlight LSTM-engression as a promising approach for incorporating uncertainty into environmental modeling. © 2026. The Author(s).

Modeling with Confidence: Leveraging Conformal Prediction for Calibrated Machine Learning Based Mechanical and Petrophysical Models

Item Type	Conference Paper
Author	W.B. Saleh
Author	B. Zhang
Abstract	Machine learning (ML) is revolutionizing reservoir characterization practices by directly using well log and drilling data. However, deterministic predictions of ML models can be misleading and result in expensive mistakes. Hence, uncertainties in ML-predicted mechanical and/or petrophysical properties need to be well quantified. By leveraging a distribution-free and computationally efficient uncertainty quantification method called Conformal Prediction (CP), we can derive calibrated ML models and quantify the uncertainties in their predictions. Several ML models are developed for permeability and elastic modulus prediction in a geothermal site in south Saskatchewan. The Catboost model outperforms other models achieving an R2 of 0.91 and 0.92 for permeability and elastic modulus, respectively. A Conformal Prediction is then built on the selected ML models to complement the predictions with valid measures of prediction intervals with 95% coverage. For a test well, where two different lab-measured permeabilities exist, more than 90% of measured permeabilities fall within the 95% prediction interval. Triaxial geomechanical test results are also comfortably within the bounds of the 95% interval. This suggests that these models provide reliable predictions with limited uncertainties. This paper underscores the crucial role of uncertainty quantification of ML-based prediction models. The study demonstrates how quantifying uncertainty can enhance our confidence in ML-predicted reservoir properties for rigorous subsurface reservoir characterization. Molecular monitoring of Dinophysis species assemblage in mussel farms in the Northwestern Adriatic Sea

Item Type Journal Article**Author** G. Ravera**Author** M. Cangini**Author** S. Capellacci**Author** S. Dall'Ara**Author** G. Prioli**Author** M. Marini**Author** E. Manini**Author** A. Penna**Author** S. Casabianca

Abstract Several Dinophysis species can produce potent lipophilic toxins that pose a risk to human health when contaminated seafood is consumed, especially filter-feeding bivalve mussels. In the mussel farms of the Northwestern Adriatic Sea, seawater and seafood are regularly monitored for the presence of Dinophysis species and their

associated toxins, but the current methodological approaches, such as light microscopy determinations, require a long time to make results available to local authorities. A molecular qPCR-based assay can be used to quantify various toxic Dinophysis species in a shorter timeframe. However, this approach is not currently employed in official testing activities. In this study, field samples were collected monthly or bi-weekly over one year from various mussel farms along the Northwestern Adriatic coast. The abundance of Dinophysis species in the seawater was determined using both traditional microscopy and qPCR assays. In addition, the concentration of lipophilic toxins for DSP in mussel flesh was quantified using LC-MS/MS focusing on the okadaic acid group. Dinophysis spp. site-specific single cells were isolated and analysed by qPCR yielding a mean rDNA copy number per cell of $1.21 \times 10^4 \pm 1.81 \times 10^3$. The qPCR assay gave an efficiency of 98 % and detected up to 10 copies of the rDNA target gene. The qPCR and light microscopy determinations in environmental samples showed a significant positive correlation (Spearman $r_s = 0.57$, $p\text{-value} < 0.001$) with a ratio of 2.24 between the two quantification methods, indicating that light microscopy estimates were generally 44.6 % lower than those obtained by the qPCR assay. The qPCR approach showed several advantages such as rapidity, sensitivity and efficiency over conventional microscopy analysis, showing its potential future role in phytoplankton monitoring under the Official Controls Regulations for shellfish. © 2024

Monitoring respiratory muscles effort during mechanical ventilation

Item Type Journal Article

Author J.P. Van Oosten

Author E. Akoumianaki

Author A.H. Jonkman

Abstract Purpose of review To summarize basic physiological concepts of breathing effort and outline various methods for monitoring effort of inspiratory and expiratory muscles. Recent findings Esophageal pressure (Pes) measurement is the reference standard for respiratory muscle effort quantification, but various noninvasive screening tools have been proposed. Expiratory occlusion pressures (P0.1 and Pocc) could inform about low and high effort and the resulting lung stress, with Pocc outperforming P0.1 in identifying high effort. The pressure muscle index during an inspiratory hold could unveil inspiratory muscle effort, however obtaining a reliable inspiratory plateau can be difficult. Surface electromyography has the potential for inspiratory effort estimation, yet this is technically challenging for real-time assessment. Expiratory muscle activation is common in the critically ill warranting their assessment, that is, via gastric pressure monitoring. Expiratory muscle activation also impacts inspiratory effort interpretation which could result in both under- and overestimation of the resulting lung stress. There is likely a future role for machine learning applications to automate breathing effort monitoring at the bedside. Summary Different tools are available for monitoring the respiratory muscles' effort during mechanical ventilation - from noninvasive screening tools to more invasive quantification methods. This could facilitate a lung and respiratory muscle-protective ventilation approach. © 2024 The Author(s). Published by Wolters Kluwer Health, Inc.

Abstract Metal powder is a key raw material for additive manufacturing (AM), with its quality directly determining the performance of AM components. Gas atomization (GA) is a dominant powder production method due to its high efficiency and cost-effectiveness, yet it frequently generates defective powders (e.g., hollow, satellite, and irregular particles) that significantly degrade the mechanical and fatigue properties of AM parts. Existing powder quality quantification methods primarily focus on particulate and bulk properties, but overlook the correlation between powder morphology and the GA process—failing to provide effective feedback for process optimization. This study aims to comprehensively evaluate GAed powders via morphological characteristic analysis. Synchrotron X-ray computed tomography (SXCT) and 3D reconstruction are used to characterize powders, which are classified into five types (irregular, satellite, normal, hollow, multi-defect) based on the formation mechanisms of defective powders in the GA process. By using 2598 powder samples and 9 morphological parameters, the machine learning models are trained. Through principal component and correlation analyses, 4 key defect-distinguishing parameters are identified, and all models achieved high accuracy. To assess GAed powders, the

particle defect distribution (PDD) is built for quality evaluation. Guided by these findings, an improved nozzle is designed, manufactured, and used for powder preparation. PDD results indicated about 300% increase in the mass ratio of normal powders with high sphericity. © 2026 Elsevier B.V.

Author Q.H. Tran**Author** T. Nguyen**Author** D. Phung**Editor** de Campos C.**Editor** Maathuis M.H.

Abstract Multi-source domain adaptation (DA) is more challenging than conventional DA because the knowledge is transferred from several source domains to a target domain. To this end, we propose in this paper a novel model for multi-source DA using the theory of optimal transport and imitation learning. More specifically, our approach consists of two cooperative agents: a teacher classifier and a student classifier. The teacher classifier is a combined expert that leverages knowledge of domain experts that can be theoretically guaranteed to handle perfectly source examples, while the student classifier acting on the target domain tries to imitate the teacher classifier acting on the source domains. Our rigorous theory developed based on optimal transport makes this cross-domain imitation possible and also helps to mitigate not only the data shift but also the label shift, which are inherently thorny issues in DA research. We conduct comprehensive experiments on real-world datasets to demonstrate the merit of our approach and its optimal transport based imitation learning viewpoint. Experimental results show that our proposed method achieves state-of-the-art performance on benchmark datasets for multi-source domain adaptation including Digits-five, Office-Caltech10, and Office-31 to the best of our knowledge. © 2021 37th Conference on Uncertainty in Artificial Intelligence, UAI 2021. Abstract Multi-source domain adaptation (DA) is more challenging than conventional DA because the knowledge is transferred from several source domains to a target domain. To this end, we propose in this paper a novel model for multi-source DA using the theory of optimal transport and imitation learning. More specifically, our approach consists of two cooperative agents: a teacher classifier and a student classifier. The teacher classifier is a combined expert that leverages knowledge of domain experts that can be theoretically guaranteed to handle perfectly source examples, while the student classifier acting on the target domain tries to imitate the teacher classifier acting on the source domains. Our rigorous theory developed based on optimal transport makes this cross-domain imitation possible and also helps to mitigate not only the data shift but also the label shift, which are inherently thorny issues in DA research. We conduct comprehensive experiments on real-world datasets to demonstrate the merit of our approach and its optimal transport based imitation learning viewpoint. Experimental results show that our proposed method achieves state-of-the-art performance on benchmark datasets for multi-source domain adaptation including Digits-five, Office-Caltech10, and Office-31 to the best of our knowledge. © 2021 Proceedings of Machine Learning Research. MOT: Masked Optimal Transport for Partial Domain Adaptation

Item Type	Conference Paper
Author	Y.-W. Luo
Author	C.-X. Ren
Abstract	As an important methodology to measure distribution discrepancy, optimal transport (OT) has been successfully applied to learn generalizable visual models under changing environments. However, there are still limitations, including strict prior assumption and implicit alignment, for current OT modeling in challenging real-world scenarios like partial domain adaptation, where the learned transport plan may be biased and negative transfer is inevitable. Thus, it is necessary to explore a more feasible OT methodology for real-world applications. In this work, we focus on the rigorous OT modeling for conditional distribution matching and label shift correction. A novel masked OT (MOT) methodology on conditional distributions is proposed by defining a mask operation with label information. Further, a relaxed and reweighting formulation is proposed to improve the robustness of OT in extreme scenarios. We prove the theoretical equivalence between conditional OT and MOT, which implies the well-defined MOT serves as a computation-friendly proxy. Extensive experiments validate the effectiveness of theoretical results and proposed model. © 2023 IEEE.

Movement imagery classification on the basis of single-trial EEGs

Item Type Conference Paper**Author** H. Maki**Author** H. Takayanagi**Author** T. Yamazaki**Author** K.-I. Kamijo**Author** T. Yamanoi

Abstract In order to develop a new brain-computer interface (BCI) using EEGs, the independent component analysis (ICA), multiple equivalent current dipole source localization (ECDL) method and then Hayashi's quantification method II were applied to single-trial EEGs during movement imagery. Up to the 20th independent component, each of them contained one or two positive (or negative) peaks in terms of 32-channel EEGs reconstructed on the electrode surface by the deflation procedure, and these peaks were analyzed by 1- or 2-dipole source localization method. Moreover, the quantification method based on these ECDL results yielded a good discrimination between right- and left-hand movement imageries, even if regardless of the time course of the localization results, instead of only for one male subject. ©2007 IEEE.

Moving shadow and object detection in traffic scenes

Item Type Journal Article

Author I. Mikić

Author P.C. Cosman

Author G.T. Kogut

Author M.M. Trivedi

Abstract We present an algorithm for segmentation of traffic scenes that distinguishes moving objects from their moving cast shadows. A fading memory estimator calculates mean and variance of all three color components for each background pixel. Given the statistics for a background pixel, simple rules for calculating its statistics when covered by a shadow are used. Then, MAP classification decisions are made for each pixel. In addition to the color features, we examine the use of neighborhood information to produce smoother classification. We also propose the use of temporal information by modifying class a priori probabilities based on predictions from the previous frame. © 2000 IEEE.

MPED: Quantifying Point Cloud Distortion Based on Multiscale Potential Energy Discrepancy

Item Type Journal Article

Author Q. Yang

Author Y. Zhang

Author S. Chen

Author Y. Xu

Author J. Sun

Author Z. Ma

Abstract In this article, we propose a new distortion quantification method for point clouds, the multiscale potential energy discrepancy (MPED). Currently, there is a lack of effective distortion quantification for a variety of point cloud perception tasks. Specifically, in human vision tasks, a distortion quantification method is used to predict human subjective scores and optimize the selection of human perception task parameters, such as dense point cloud compression and enhancement. In machine vision tasks, a distortion quantification method usually serves as loss function to guide the training of deep neural networks for unsupervised learning tasks (e.g., sparse point cloud reconstruction, completion, and upsampling). Therefore, an effective distortion quantification should be differentiable, distortion discriminable, and have low computational complexity. However, current distortion quantification cannot satisfy all three conditions. To fill this gap, we propose a new point cloud

feature description method, the point potential energy (PPE), inspired by classical physics. We regard the point clouds are systems that have potential energy and the distortion can change the total potential energy. By evaluating various neighborhood sizes, the proposed MPED achieves global-local tradeoffs, capturing distortion in a multiscale fashion. We further theoretically show that classical Chamfer distance is a special case of our MPED. Extensive experiments show that the proposed MPED is superior to current methods on both human and machine perception tasks. Our code is available at <https://github.com/Qi-Yangsjtu/MPED>. © 1979-2012 IEEE.

MRI Voxel-Based Morphometry to Classify Brain Structural Alterations in Parkinson's Disease

Item Type Conference Paper

Author S. Datta

Author M.K. Acharaya

Author B. Chakrabarty

Author N. Ghosh

Abstract The introduction of voxel-based morphometry (VBM) has profoundly impacted neuroimaging, offering a robust and objective approach to analyze brain structure using MRI. This study presents a customized pipeline for VBM methodology and its applications in both healthy elderly individuals and patients with Parkinson's disease (PD). The VBM process mainly involves spatial normalization to a standard template, segmentation into gray matter (GM) and white matter (WM), smoothing, and rigorous statistical analysis. VBM has proven invaluable in detecting subtle brain structural changes in various neurological and psychiatric conditions, as well as identifying gross structural abnormalities. The study highlights VBM's crucial role in advancing neuroimaging research, making it an indispensable tool in the field. While VBM has significantly advanced our understanding of brain morphology, careful attention to the algorithmic implementation is essential to ensure the accuracy of conclusions about anatomical differences related to disease states. This study underscores that combining VBM with complementary neuroimaging techniques can greatly enhance our understanding of normal brain processes and improve comparisons between patient and control groups. This study deals with 12 healthy controls (HCs) and 30 PD patients. It is concluded that a more effective biomarker could be prepared with the help of suggested pipeline of automated VBM without custom templates and custom tissue class priors. © 2024 IEEE.

Abstract We introduce a new R package “MrIML” (“Mister iml”; Multi-response Interpretable Machine Learning). MrIML provides a powerful and interpretable framework that enables users to harness recent advances in machine learning to quantify multilocus genomic relationships, to identify loci of interest for future landscape genetics studies, and to gain new insights into adaptation across environmental gradients. Relationships between genetic variation and environment are often nonlinear and interactive; these characteristics have been challenging to address using traditional landscape genetic approaches. Our package helps capture this complexity and offers functions that fit and interpret a wide range of highly flexible models that are routinely used for single-locus landscape genetics studies but are rarely extended to estimate response functions for multiple loci. To demonstrate the package's broad functionality, we test its ability to recover landscape relationships from simulated genomic data. We also apply the package to two empirical case studies. In the first, we model genetic variation of North American balsam poplar (*Populus balsamifera*, Salicaceae) populations across environmental gradients. In the second case study, we recover the landscape and host drivers of feline immunodeficiency virus genetic variation in bobcats (*Lynx rufus*). The ability to model thousands of loci collectively and compare models from linear regression to extreme gradient boosting, within the same analytical framework, has the potential to be transformative. The MrIML framework is also extendable and not limited to modelling genetic variation; for example, it can quantify the environmental drivers of microbiomes and coinfection dynamics. © 2021 John Wiley & Sons Ltd

Multi-atlas segmentation and quantification of muscle, bone and subcutaneous adipose tissue in the lower leg using peripheral quantitative computed tomography

Item Type Journal Article

Author S. Makrogiannis

Author A. Okorie

Author A. Di Iorio

Author S. Bandinelli

Author L. Ferrucci

Abstract Accurate and reproducible tissue identification is essential for understanding structural and functional changes that may occur naturally with aging, or because of a chronic disease, or in response to intervention therapies. Peripheral quantitative computed tomography (pQCT) is regularly employed for body composition studies, especially for the structural and material properties of the bone. Furthermore, pQCT

acquisition requires low radiation dose and the scanner is compact and portable. However, pQCT scans have limited spatial resolution and moderate SNR. pQCT image quality is frequently degraded by involuntary subject movement during image acquisition. These limitations may often compromise the accuracy of tissue quantification, and emphasize the need for automated and robust quantification methods. We propose a tissue identification and quantification methodology that addresses image quality limitations and artifacts, with increased interest in subject movement. We introduce a multi-atlas image segmentation (MAIS) framework for semantic segmentation of hard and soft tissues in pQCT scans at multiple levels of the lower leg. We describe the stages of statistical atlas generation, deformable registration and multi-tissue classifier fusion. We evaluated the performance of our methodology using multiple deformable registration approaches against reference tissue masks. We also evaluated the performance of conventional model-based segmentation against the same reference data to facilitate comparisons. We studied the effect of subject movement on tissue segmentation quality. We also applied the top performing method to a larger out-of-sample dataset and report the quantification results. The results show that multi-atlas image segmentation with diffeomorphic deformation and probabilistic label fusion produces very good quality over all tissues, even for scans with significant quality degradation. The application of our technique to the larger dataset reveals trends of age-related body composition changes that are consistent with the literature. Because of its robustness to subject motion artifacts, our MAIS methodology enables analysis of larger number of scans than conventional state-of-the-art methods. Automated analysis of both soft and hard tissues in pQCT is another contribution of this work. Copyright © 2022 Makrogiannis, Okorie, Di Iorio, Bandinelli and Ferrucci.

Multi-Attribute Decision Making (MADM) Model Based on Bayesian Neural Network Classification with Comparative Scoring Quantification Method Can Solve Intangible Value Valuation Issues in Benefit-Cost Analysis (BCA)

Item Type Conference Paper

Author Z. Wang

Author H.-H. Wang

Editor Huang K.-W.

Editor Cao Q.

Editor Su R.

Abstract This paper is Methodology research of Benefit-Cost Analysis (BCA) under machine learning-driven Classification Bayesian Neural Network. BCA is currently the predominant decision-making tool for corporate capital investment. Due to its inherent single-metric nature, BCA lacks complete quantifiability and responsiveness in terms of intangible benefits and ethics. In this paper the author presents how advanced AI scoring algorithm enables Multi-Attribute Decision Making (MADM) approach to dissolve monetization failure issue stemming from ethical concerns in Benefit-Cost Analysis (BCA). In the current context of increasing emphasis on Corporate Social Responsibility (CSR), ethical considerations have become vital for businesses. Therefore, it is advisable to utilize machine learning leveraging the business big data to train more sophisticated and stable multi-dimensional decision-making models, then integrate them into the framework of BCA, thereby evolving the BCA methodology to overcome its drawbacks. The three main problems associated with BCA discussed are: (1) intangible value is difficult to monetize, and (2) human life-related benefits should not be monetized due to the ethical principle. And (3) the normative and distributional problem of BCA that cannot take into account both the efficiency criterion and the equity criterion in one decision-making process. For the three problems of BCA, author introduces a Bayesian Neural Network Scoring algorithm based Analytic Hierarchy Process (AHP) to achieve Multi-Attribute Decision Making (MADM) and explains why it can solve the above three problems that are difficult for BCA to handle solely. Furthermore, arguing the limitations of such AHP-MADM methodology and puts forward the improvement methods including the Expected Utility Theory [1], and VIKOR method based on “Prospect Theory” [2, 3] which allow each organization to have its own unique decision preferences. © The Author(s), under exclusive license to Springer Nature Singapore Pte Ltd. 2025.

Multi-class Classification from Multiple Unlabeled Datasets with Partial Risk Regularization

Item Type Conference Paper

Author Y. Tang

Author N. Lu

Author T. Zhang

Author M. Sugiyama

Editor Khan E.

Editor Gonen M.

Abstract Recent years have witnessed a great success of supervised deep learning, where predictive models were trained from a large amount of fully labeled data. However, in practice, labeling such big data can be very costly and may not even be possible for privacy reasons. Therefore, in this paper, we aim to learn an

accurate classifier without any class labels. More specifically, we consider the case where multiple sets of unlabeled data and only their class priors, i.e., the proportions of each class, are available. Under this problem setup, we first derive an unbiased estimator of the classification risk that can be estimated from the given unlabeled sets and theoretically analyze the generalization error of the learned classifier. We then find that the classifier obtained as such tends to cause overfitting as its empirical risks go negative during training. To prevent overfitting, we further propose a partial risk regularization that maintains the partial risks with respect to unlabeled datasets and classes to certain levels. Experiments demonstrate that our method effectively mitigates overfitting and outperforms state-of-the-art methods for learning from multiple unlabeled sets. © 2022 Y. Tang, N. Lu, T. Zhang & M. Multi-Class Machine Learning to Quantify the Impact of Nitrogen Management Practices on Grassland Biomass

Item Type Journal Article

Author S. Raubitzek

Author M. Hartlieb

Author P. König

Author J. Hinderling

Author K. Mallinger

Abstract Grassland biomass yield reflects a complex interaction of management intensity and environmental factors, yet quantifying the relative role of practices such as mowing and fertilization remains challenging. In this study, we introduce a multi-class machine learning framework to predict above-ground biomass on 150 permanent grassland plots across eight years (2009–2016) in Germany’s Biodiversity Exploratories and to evaluate the influence of key management variables. Following rigorous data cleaning, imputation of missing nitrogen values, feature standardization, and encoding of categorical practices, we trained CatBoost classifiers optimized via Bayesian hyperparameter search and mitigated class imbalance with ADASYN oversampling. We assessed model performance under binary, three-class, four-class, and five-class quantile-based categorizations, achieving test accuracies of 0.76, 0.57, 0.42, and 0.38, respectively. Across all schemes, mowing frequency and mineral nitrogen input emerged as the dominant predictors, while secondary variables such as drainage and conditioner use contributed as well. These results demonstrate that broad biomass categories can be forecast reliably from standardized management records, whereas finer distinctions necessitate additional environmental information or automated sensing to capture nonlinear effects and reduce reporting bias. This work shows both the potential and the limits of machine learning for informing sustainable grassland management and explainability thereof. Frequent mowing and higher mineral nitrogen inputs explained most of the predictable variation, enabling a 76% accurate separation of low and high biomass categories. Predictive accuracy fell below 60% for finer class resolutions, indicating that management records alone are insufficient for detailed yield forecasts without complementary environmental data. © 2025 by the authors.

MULTI-CLASS UNCERTAINTY CALIBRATION VIA MUTUAL INFORMATION MAXIMIZATION-BASED BINNING

Item Type Conference Paper

Author K. Patel

Author W. Beluch

Author B. Yang

Author M. Pfeiffer

Author D. Zhang

Abstract Post-hoc multi-class calibration is a common approach for providing high-quality confidence estimates of deep neural network predictions. Recent work has shown that widely used scaling methods underestimate their calibration error, while alternative Histogram Binning (HB) methods often fail to preserve classification accuracy. When classes have small prior probabilities, HB also faces the issue of severe sample-inefficiency after the conversion into K one-vs-rest class-wise calibration problems. The goal of this paper is to resolve the identified issues of HB in order to provide calibrated confidence estimates using only a small holdout calibration dataset for bin optimization while preserving multi-class ranking accuracy. From an information-theoretic perspective, we derive the I-Max concept for binning, which maximizes the mutual information between labels and quantized logits. This concept mitigates potential loss in ranking performance due to lossy quantization, and by disentangling the optimization of bin edges and representatives allows simultaneous improvement of ranking and calibration performance. To improve the sample efficiency and estimates from a small calibration set, we propose a shared class-wise (sCW) calibration strategy, sharing one calibrator among similar classes (e.g., with similar class priors) so that the training sets of their class-wise calibration problems can be merged to train the single calibrator. The combination of sCW and I-Max binning outperforms the state of the art calibration methods on various evaluation metrics across different benchmark datasets and models, using a small calibration set (e.g., 1k samples for ImageNet). © 2021 ICLR 2021 - 9th International Conference on Learning Representations. Multi-classification recognition and quantitative characterization of surface defects in belt grinding based on YOLOv7

Item Type Journal Article

Author B. Zhu

Author G. Xiao

Author Y. Zhang

Author H. Gao

Abstract Due to the complex and varied surface defects of the belt grinding, the automatic recognition and quantitative characterization of the surface defects is still an issue that needs to be resolved. To characterize surface defects in belt grinding, this study proposed a multi-classification recognition and quantification method. The YOLOv7 algorithm was utilized to detect defects, which would obtain classification and location information of defects. Aiming at the defects with continuous geometric boundaries, an object detection strategy based on Hough straight-line image correction was designed to quantitatively describe the characteristics of the defects in the grinding direction. In order to capture the quantitative information of burn defects without continuous geometric boundaries, an adaptive threshold segmentation approach with correction factors was developed. The results demonstrated that the YOLOv7 performance on our dataset reaches the mAP of 0.907. The suggested quantitative characterization method can effectively quantitatively characterize and analyze the defects. © 2023 Elsevier Ltd

Multi-cohort Sleep EEG-based Depression Detection Using Multi-modal Data from the National Sleep Research Resource

Item Type Conference Paper
Author M. Mohtashamian
Author X. Li
Author L. Rasmy
Author L. Cui
Abstract Depression is a highly prevalent mental health disorder that significantly impairs quality of life and functional capacity. Accurate and timely identification is essential to support effective clinical intervention and long-term management. This study examines the potential of integrating multiple cohorts from the National Sleep Research Resource (NSRR) for depression detection based on multi-modal sleep electroencephalogram (EEG), demographic, and clinical data. We integrated three NSRR cohorts comprising 1,288 individuals (209 depressed and 1,079 non-depressed). Overnight sleep EEG recordings from C3/C4 electrode channels were used to characterize sleep-related neurophysiological patterns, together with demographic and clinical variables. To optimize predictive performance, feature selection was performed using Least Absolute Shrinkage

and Selection Operator (LASSO), followed by evaluation using multiple classical machine learning and deep learning models. Predictive models were developed and evaluated using a rigorous validation framework to assess generalizability across heterogeneous datasets. Our best-performing models achieved an area under the receiver operating characteristic curve (AUROC) of up to 0.688 with area under the precision-recall curve (AUPRC) up to 0.327 on the imbalanced cohort (positive-class prevalence ≈ 0.162), exceeding the random baseline expected under class imbalance. Although conservative relative to small-sample studies, these results reflect improved generalizability enabled by the large cohort size, multi-cohort design, and a strictly leakage-free evaluation in which feature selection is performed within each training fold. Overall, the findings demonstrate the feasibility of using multi-modal data from NSRR to support scalable and generalizable approaches for sleep EEG-based depression detection. © 2026 IEEE.

Multi-instance positive and unlabeled learning with bi-level embedding

Item Type Journal Article

Author X. Tang

Author C. Xu

Author T. Luo

Author C. Hou

Abstract Multiple Instance Learning (MIL) is a widely studied learning paradigm which arises from real applications. Existing MIL methods have achieved prominent performances under the premise of plenty annotation data. Nevertheless, sufficient labeled data is often unattainable due to the high labeling cost. For example, the task in web image identification is to find similar samples among a large size of unlabeled dataset through a small number of provided target pictures. This leads to a particular scenario of Multiple Instance Learning with insufficient Positive and superabundant Unlabeled data (PU-MIL), which is a hot research topic in MIL recently. In this paper, we propose a novel method called Multiple Instance Learning with Bi-level Embedding (MILBLE) to tackle PU-MIL problem. Unlike other PU-MIL method using only simple single-level mapping, the bi-level embedding strategy are designed to customize specific mapping for positive and unlabeled data. It ensures the characteristics of key instance are not erased. Moreover, the weighting measure adopted in positive data can extracts the uncontaminated information of true positive instances without interference from negative ones. Finally, we minimize the classification error loss of mapped examples based on class-prior probability to train the optimal classifier. Experimental results show that our method has better performance than other state-of-the-art methods. © 2022 - IOS Press. All rights reserved.

Multi-Label Quantification

Item Type Journal Article

Author A. Moreo

Author M. Francisco

Author F. Sebastiani

Abstract Quantification, variously called supervised prevalence estimation or learning to quantify, is the supervised learning task of generating predictors of the relative frequencies (a.k.a. prevalence values) of the classes of interest in unlabelled data samples. While many quantification methods have been proposed in the past for binary problems and, to a lesser extent, single-label multiclass problems, the multi-label setting (i.e., the scenario in which the classes of interest are not mutually exclusive) remains by and large unexplored. A straightforward solution to the multi-label quantification problem could simply consist of recasting the problem as a set of independent binary quantification problems. Such a solution is simple but naïve, since the independence assumption upon which it rests is, in most cases, not satisfied. In these cases, knowing the relative frequency of one class could be of help in determining the prevalence of other related classes. We propose the first truly multi-label quantification methods, i.e., methods for inferring estimators of class prevalence values that strive to leverage the stochastic dependencies among the classes of interest in order to predict their relative frequencies more accurately. We show empirical evidence that natively multi-label solutions outperform the naïve approaches by a large margin. The code to reproduce all our experiments is available online. © 2023 Copyright held by the owner/author(s). Publication rights licensed to ACM.

MULTI-LEVEL AUGMENTATION CONSISTENCY LEARNING AND SAMPLE SELECTION FOR SEMI-SUPERVISED DOMAIN GENERALIZATION

Item Type Conference Paper

Author M. Yu

Author Y. Zhang

Author X. Li

Author R. Zhang

Author H. Jiang

Author J. Gao

Author Z. Liu

Abstract Semi-supervised domain generalization (SSDG) aims to build a domain-generalized model using partially labeled data from source domains. Mainstream SSDG methods follow the augmentation consistency in FixMatch. However, the extraction of domain-invariant features may be challenging due to the absence of feature-based operations, further leading to overfitting of the classifier. To this end, we propose Multi-level Augmentation Consistency Learning (MACMatch), which improves the generalization of feature extractor and classifier through feature-based augmentation consistency. On the other hand, existing methods assume labeled data are class-balanced and domain-balanced, which is easily violated in practice. Based on this, we introduce Representativity and Diversity-based Sample Selection (RDSS), which models data as graphs to evaluate reasonable samples for labeling, relaxing the assumption for labeled data. Experiments on PACS and OfficeHome demonstrate that MACMatch outperforms state-of-the-art SSDG methods. Furthermore, MACMatch with RDSS achieves competitive results without domain and class priori assumptions. Code is available at <https://github.com/Y-J-Zhang/MACMatch-RDSS>. ©2024 IEEE.

Multi-objective Learning to Overcome Catastrophic Forgetting in Time-series Applications

Item Type Journal Article**Author** R.A. Mahmoud**Author** H. Hajj

Abstract One key objective of artificial intelligence involves the continuous adaptation of machine learning models to new tasks. This branch of continual learning is also referred to as lifelong learning (LL), where a major challenge is to minimize catastrophic forgetting, or forgetting previously learned tasks. While previous work on catastrophic forgetting has been focused on vision problems; this work targets time-series data. In addition to choosing an architecture appropriate for time-series sequences, our work addresses limitations in previous work, including the handling of distribution shifts in class labels. We present multi-objective learning with three loss functions to minimize catastrophic forgetting, prediction error, and errors in generalizing across label shifts, simultaneously. We build a multi-task autoencoder

network with a hierarchical convolutional recurrent architecture. The proposed method is capable of learning multiple time-series tasks simultaneously. For cases where the model needs to learn multiple new tasks, we propose sequential learning, starting with tasks that have the best individual performances. This solution was evaluated on four benchmark human activity recognition datasets collected from mobile sensing devices. A wide set of baseline comparisons is performed, and an ablation analysis is run to evaluate the impact of the different losses in the proposed multi-objective method. The results demonstrate an up to 4% performance improvement in catastrophic forgetting compared to the use of loss functions in state-of-the-art solutions while demonstrating minimal losses compared to upper bound methods of traditional fine-tuning (FT) and multi-task learning (MTL). © 2022 Association for Computing Machinery.

Multi-Source Remote Sensing Data Fusion for Aboveground Biomass Estimation in Tropical Forests: Recent Advances, Challenges, and Future Trends

Item Type Journal Article

Author Q. Meng

Author Y.-B. Leau

Author J. Shi

Author J. Zhou

Abstract Accurate estimation of aboveground biomass (AGB) in tropical forests is critical for global carbon cycle research and climate policies such as REDD+, but single remote sensing sources face limitations: optical sensors suffer from saturation and cloud interference, SAR has saturation and terrain-induced distortions, and lidar (e.g., GEDI) provides high-precision vertical structures but sparse coverage. Multi-source data fusion - including data-level, feature-level, decision-level fusion, and spatio-temporal scaling - leverages the complementary strengths of optical, SAR, and LiDAR data to mitigate these issues, machine learning (e.g., RF, XGBoost) and deep learning (e.g., CNN, Transformer) to improve performance, and hybrid models to balance learning ability and robustness. Key challenges including data heterogeneity, geometric/radiometric inconsistencies, saturation in dense forests, cloud-induced optical data loss, and sparse GEDI footprints are addressed through validation frameworks (involving forest maps, NFI, airborne LiDAR) and uncertainty quantification methods (e.g., spatial cross-validation, Monte Carlo simulations). Regional case studies (Amazon, Congo Basin, Southeast Asia) show optimal strategies for specific environments, while future directions focus on collaborative GEDI with P-band SAR, dynamic monitoring through temporal fusion, physical based deep learning, federated/transfer learning, interpretable AI, and standardized REDD+ protocols. Based on a systematic review of AGB estimation studies in tropical forests in the past five years, this paper summarizes the development progress of multi-source remote sensing data fusion and advanced algorithms, identifies the existing technical bottlenecks, and proposes a future-oriented comprehensive optimization framework to improve the accuracy and robustness of AGB estimation. © 2013 IEEE.

Multi-Target Detection in Underwater Sensor Networks Based on Bayesian Deep Learning

Item Type Journal Article**Author** X. Du**Author** Y. Wen**Author** J. Yan**Author** Y. Zhang**Author** X. Luo**Author** X. Guan

Abstract Underwater target detection and its development have an important role in advancing marine science and technology. However, the complex and dynamic underwater environment poses challenges for detecting non-cooperative targets. This paper focuses on the problem of detecting and recognizing multiple non-cooperative targets in USNs. Specifically, the generative model is firstly utilized to learn the probability distribution of underwater signals, and then Bayesian fusion of active and passive measurements is utilized to achieve target detection. Along with this, a Bayesian deep learning classification framework is employed to categorize multiple targets. Compared to the traditional statistical detection methods, our method excels in handling underwater complexity and dynamics. In addition, unlike traditional deep learning, our classification framework combines Bayesian inference with deep learning to quantify environmental uncertainty. This approach helps the model perform more robust detection and improves the management of noise and uncertainty. Experimental and simulation analysis demonstrate the effectiveness of Bayesian deep learning methods in solving the challenges of underwater target detection. These findings highlight the potential of our approach in enhancing sensing and surveillance capabilities in complex underwater environments. © 2013 IEEE.

Multi-Task Attention-Guided Deep Learning for Simultaneous Breast Cancer Detection and Density Estimation in Mammography

Item Type Journal Article**Author** G. Esen**Author** M. Nurtas**Author** L. la Paglia**Author** J. Amankulov**Author** B. Matkerim**Author** A. Altaibek

Abstract Early detection of breast cancer is critical for improving patient outcomes, and deep learning (DL) has shown promise in mammographic analysis. However, many existing systems tackle a single task (e.g., malignancy classification) and provide limited interpretability, which hinders clinical adoption. We present a multi-task, attention-guided framework that jointly predicts malignancy (benign vs. malignant) and BI-RADS breast density (A–D) from a single mammogram while producing interpretable attention maps. The architecture couples a pretrained convolutional backbone with lightweight channel–spatial attention and two task-specific heads. We evaluate six backbones (ResNet-50, DenseNet-121, EfficientNet-B0/B3/B7, MobileNetV3-Large) under a rigorous evaluation protocol with stratified hold-out split (64%/16%/20%) and 5-fold cross-validation. To support reliable deployment, we report comprehensive metrics including discrimination measures (ROC-AUC, PR-AUC, F1-score, sensitivity, specificity), calibration metrics (Brier score, Expected

Calibration Error), and ablation studies contrasting single-task vs. multi-task learning and models with vs. without attention mechanisms. Across all evaluation protocols, multi-task learning consistently outperforms single-task baselines by 2.8% in pathology accuracy and 3.5% in density estimation, indicating that density cues provide complementary information for malignancy assessment. Among backbones, EfficientNet-B3 attains the strongest discrimination (AUC= 0.962, accuracy= 93.6%) on hold-out test with excellent calibration (Brier= 0.010), while MobileNetV3-Large achieves competitive performance (AUC= 0.940, accuracy= 91.2%) with only 4.26M parameters—an optimal accuracy–efficiency trade-off for resource-constrained deployment. Cross-validation results demonstrate robust generalization (AUC = 0.954 ± 0.003 , accuracy = $93.0 \pm 0.3\%$). Attention maps highlight diagnostically relevant regions including architectural distortions and suspicious calcifications, offering interpretable visual rationale aligned with radiological assessment. We discuss limitations including dataset size (410 images), class imbalance in rare density categories, and calibration challenges (ECE= 0.365–0.419), and outline directions for external validation on multi-institutional cohorts and integration of uncertainty quantification methods. © 2013 IEEE.

Abstract With the increasing penetration of renewable energy there is an urgent need to consider the influence of renewable generation forecast errors on the reserve requirement. In the paper, referring to the multi-time scale classification system for reserve resources based on their response times, a multi-time scale reserve requirement quantification method is proposed based on based on Empirical Mode Decomposition (EMD). In this method, the net load forecast error samples are decomposed into multiple fluctuation components. Based on the dominant period, the fluctuation components are subjected to envelope reconstruction, thereby quantifying the multi-time scale reserve requirement. Finally, case studies on net load forecast error curve samples are presented, and the result shows that the proposed model can effectively optimize the allocation of multitime scale reserve requirement, reduces reserve overestimation. Through the calculation of reserve requirements at various renewable penetration rate, proactive adjustments to reserve requirement can be made, guiding grid planning efforts. © 2026 IEEE.

Multiclass microarray data classification based on confidence evaluation

Item Type Journal Article

Author H.L. Yu

Author S. Gao

Author B. Qin

Author J. Zhao

Abstract Microarray technology is becoming a powerful tool for clinical diagnosis, as it has potential to discover gene expression patterns that are characteristic for a particular disease. To date, this possibility has received much attention in the context of cancer research, especially in tumor classification. However, most published articles have concentrated on the development of binary classification methods while neglected ubiquitous multiclass problems. Unfortunately, only a few multiclass classification approaches have had poor predictive accuracy. In an effort to improve classification accuracy, we developed a novel multiclass microarray data classification method. First, we applied a "one versus rest-support vector machine" to classify the samples. Then the classification confidence of each testing sample was evaluated according to its distribution in feature space and some with poor confidence were extracted. Next, a novel strategy, which we named as "class priority estimation method based on centroid distance", was used to make decisions about categories for those poor confidence samples. This approach was tested on seven benchmark multiclass microarray datasets, with encouraging results, demonstrating effectiveness and feasibility. ©FUNPEC-RP.

Multidimensional analysis and predictive modeling of cognitive decline risk in the United States using propensity score matching and machine learning

Item Type Journal Article

Author J. Li

Author G. Chen

Author Y. Liu

Abstract Cognitive decline, an early indicator of neurodegenerative disorders, presents a growing public health challenge. This study aimed to integrate causal inference and machine learning to quantify the causal impact of high-risk status on cognitive function, explore geographic and temporal heterogeneity, and develop predictive models for early identification of at-risk individuals in the United States. We analyzed 22,182 records from the behavioral risk factor surveillance system. Causal effects were estimated using propensity score matching and doubly robust estimation to mitigate confounding. Geographic and temporal heterogeneity were assessed through stratified analyses. Predictive models were developed using random forest and XGBoost, trained on 80% of the dataset and evaluated on 20%, with performance assessed by accuracy, precision, recall, and F1 score. Propensity score matching estimated an average treatment effect (ATE) of 19.92 points (95% confidence interval: 19.70–20.15), and doubly robust estimation yielded an ATE of 16.95 points (95% confidence interval: 16.77–17.14), confirming a significant causal link between high-risk status and cognitive decline. Regional heterogeneity was pronounced, with

US territories showing the highest ATE (59.40). Temporal analysis from 2015 to 2022 revealed no significant overall trend ($P = .54$), although annual fluctuations were observed. The random forest model achieved the best predictive performance (accuracy = 0.77, $F1 = 0.67$), outperforming XGBoost in balancing precision and recall. The findings demonstrate a significant causal relationship between high-risk status and cognitive decline, with marked geographic disparities. The integration of causal inference with machine learning provides a robust framework for both understanding risk factors and building practical screening tools. These results offer actionable insights for targeting public health interventions and underscore the potential of data-driven approaches in cognitive health management. Multilevel Feature Score Learning for Few-Shot Open-Set Recognition of Hyperspectral Images

Item Type Journal Article

Author Z. Zhang

Author Z. Li

Author Y. Wang

Author X. Gong

Author J. Guo

Author J. Tian

Abstract Few-shot open-set recognition (FSOSR) for hyperspectral images (HSIs) is a challenging task of great practical value. It aims to classify a sample to one of the known classes by few examples while being able to reject the sample from unknown classes. Prior research mainly focuses on high-level semantic features and ignores mid-level and low-level detailed features. Furthermore, recent endeavors in generative few-shot open-set recognition (FSOSR) have the limitation that the generated samples do not accurately reflect the original data distribution and introduce additional noise. To solve these problems, a novel FSOSR method for HSI based on multilevel feature score learning (MFSL) is proposed, which considers multilevel features and combines semantic information with detailed information. By designing the multilayer score fusion (MSF) module, the similarity of multilevel features and prototypes is converted into scores, so that the score of known samples is lower and the score of unknown samples is higher. The intra–inter similarity contrast enhancement (ISCE) module is also introduced to enhance the discrimination of features, increasing the intraclass similarity while decreasing the interclass similarity by adjusting the similarity of known samples and prototypes. Experiments on two HSI datasets verify the effectiveness of MFSL. © 2004-2012 IEEE.

Abstract Metal fatigue cracks under cyclic loading conditions cannot be ignored. Ultrasound-induced thermography has been emerged as an effective technique for crack detection, however, single-frequency ultrasound excitation often produces weak thermal signals, especially for small or shallow cracks, limiting identification accuracy. To overcome these challenges, Multimodal Algorithm-enhanced Chirped

Ultrasound-Induced Thermography (MA-CUIT) was proposed for quantitative crack characterization. Firstly, metal cracks three-dimensional thermal-wave model under chirp excitation was established to analyze temperature distribution and thermal diffusion. Subsequently, a comprehensive feature extraction framework integrating frequency-domain, time-domain, and machine learning methods was developed under chirp ultrasound excitation, with systematic optimization of frequency modulation parameters to determine optimal excitation ranges. MA-CUIT experimental platform was established for quantification of real crack defects. The results indicate that MA-CUIT, achieved exceptional crack sizing accuracy with relative errors of 5.9% (FFT phase optimized), 6.7% (PLSR 1st coefficient optimized), and 6.3% (DOD phase optimized), establishing MA-CUIT optimized by FFT phase analysis as the most precise quantification method. © 2025

Multimodal out-of-distribution individual uncertainty quantification enhances binding affinity prediction for polypharmacology

Item Type Journal Article

Author A. Badkul

Author L. Xie

Author S. Zhang

Author L. Xie

Abstract Polypharmacology, a single drug that targets multiple proteins, holds promise for addressing unmet medical needs. Achieving accurate, reliable and scalable predictions of protein–ligand binding affinity across multiple proteins is crucial to realizing the potential of polypharmacology. Machine learning offers a powerful tool for multitarget binding affinity prediction. However, three major challenges remain: generalizing predictions to out-of-distribution compounds that are structurally different from those in the training data; quantifying the uncertainty of predictions in out-of-distribution scenarios where the assumption underlying existing methods does not hold; and scaling to billions of compounds, which remains unattainable for current structure-based methods. Here, to overcome these challenges, we propose a model-agnostic anomaly detection-based individual uncertainty quantification method: embedding Mahalanobis Outlier Scoring and Anomaly Identification via Clustering (eMOSAIC). eMOSAIC features the divergence between the multimodal representations of known cases and unseen instances and quantifies individual prediction uncertainty on a compound-by-compound basis. We integrate eMOSAIC with a multimodal deep neural network for multitarget ligand binding affinity predictions, leveraging a structure-informed large protein language model. Comprehensive validation in out-of-distribution settings demonstrates that eMOSAIC significantly outperforms state-of-the-art sequence-based and structure-based methods as well as existing uncertainty quantification approaches. These findings underscore eMOSAIC’s potential to advance real-world polypharmacology and other applications that require robust predictions and scalable solutions. © The Author(s), under exclusive licence to Springer Nature Limited 2025.

Multioriented video scene text detection through bayesian classification and boundary growing

Item Type Journal Article

Author P. Shivakumara

Author R.P. Sreedhar

Author T.Q. Phan

Author S. Lu

Author C.L. Tan

Abstract Multioriented text detection in video frames is not as easy as detection of captions or graphics or overlaid texts, which usually appears in the horizontal direction and has high contrast compared to its background. Multioriented text generally refers to scene text that makes text detection more challenging and interesting due to unfavorable characteristics of scene text. Therefore, conventional text detection methods may not give good results for multioriented scene text detection. Hence, in this paper, we present a new enhancement method that includes the product of Laplacian and Sobel operations to enhance text pixels in videos. To classify true text pixels, we propose a Bayesian classifier without assuming a priori probability about the input frame but estimating it based on three probable matrices. Three different ways of clustering are performed on the output of the enhancement method to obtain the three probable matrices. Text candidates are obtained by intersecting the output of the Bayesian classifier with the Canny edge map of the input frame. A boundary growing method is introduced to traverse the multioriented scene text lines using text candidates. The boundary growing method works based on the concept of nearest neighbors. The robustness of the method has been tested on a variety of datasets that include our own created data (nonhorizontal and horizontal text data) and two publicly available data, namely, video frames of Hua and complex scene text data of ICDAR 2003 competition (camera images). Experimental results show that the performance of the proposed method is encouraging compared with results of existing methods in terms of recall, precision, F-measures, and computational times. © 2012 IEEE.

Multiple imputation of missing data using efficient machine learning approach

Item Type Journal Article

Author S. Kanchana

Author A.S. Thanamani

Abstract Missing values are an unavoidable problem in dealing with most of the real world data sources, and the missing values in a dataset may affect the quality of the supervised learning process. This paper focuses machine learning techniques Naïve Bayesian Classifier method for the imputation of missing values in large datasets. Single value imputation produce biased results, whereas multiple imputation generates right value to replace. The study was conducted to implement several algorithms in unsupervised techniques like Mean, Median, Standard Deviation, and Regression and supervised machine learning techniques like Naïve Bayesian classifier provides different methods to calculate Class prior probability, Posterior probability, Predictor probability and Maximum Likelihood. Both methods are trying to find hidden structure in unlabeled data. The performance of this method has been compared by using Correlation statistics analysis which produces the imputed values are positively related or negatively related or not related with each other. To evaluate the performance, the standard machine learning repository dataset has been used. We

experimentally shows that our approach significantly outperforms some standard machine learning methods for handling missing values in classification tasks. © Research India Publications.

Multiple Summary Knowledge-Based Disease Prevalence Estimation for Group Testing Data

Item Type Journal Article

Author W. Yang

Author J. Ding

Author W. Xiong

Author S. Wang

Author Q. Li

Abstract Group testing is widely recognized for its ability to reduce time and cost in screening for rare diseases. However, with limited samples, the parameter estimation from group-testing data might be inefficient. In some scenarios, the external summary statistics are available. To make full use of them, we propose a multiple-source knowledge transfer method. The resulting prevalence estimator is consistent and more efficient than the conventional estimator based on the target group-testing data alone. We establish the asymptotic normality of the proposed estimator. In addition, we develop a data-driven screening procedure to identify the transferable sources. We extend this framework to Dorfman's two-stage group testing design and show that integrating the retesting data yields efficiency gains. The asymptotic normality of the corresponding estimator is also established. Extensive simulations and a real-data

application support the theoretical results and demonstrate the favorable finite-sample performance of the proposed method. © 2026 John Wiley & Sons Ltd.

Multiscale 1-DCNN for Damage Localization and Quantification Using Guided Waves With Novel Data Fusion Technique and New Self-Attention Module

Item Type Journal Article

Author Y. Liao

Author Y. Wang

Author X. Zeng

Author M. Wu

Author X. Qing

Abstract This article proposes an innovative damage localization and size quantification method named as MSCNNSAM based on a new multiscale convolutional neural network (MSCNN) and novel small-weighted zero-setting self-attentive module (SAM) in carbon fiber reinforced plastic structures. First, an improved piecewise aggregate approximation algorithm (IPAA) is developed to compress the guided wave signal and extract a series of damage indexes (DI). Considering the different effects of the damage location on the different sensing paths, a new method of damage information targeting enhancement and multipath data fusion is proposed. Then, a novel MSCNN architecture is also proposed for the inherent multiscale characteristics of the guided wave signal, which takes the multipath fused data as input and uses regression and classification methods to directly predict the location and size of the damage. Finally, to further improve the performance of the MSCNN, a SAM is proposed to effectively avoid the influence of low-information channel features and improve the damage feature extraction capability of the network. The proposed method is evaluated through experiments on a guided wave testing platform. Experimental results and a comprehensive comparison analysis with respect to the state-of-the-art damage localization and quantification. methods have demonstrated the superiority of the proposed MSCNNSAM. © 2005-2012 IEEE.

Abstract Dilated cardiomyopathy is a progressive irreversible disease associated with contractile dysfunction and heart failure. During dilated cardiomyopathy, elevated diastolic wall strains trigger mechanotransduction pathways that initiate the addition of sarcomeres in series and an overall increase in myocyte length. At the whole organ level, this results in a chronic dilation of the ventricles, an increase in end diastolic and end systolic volumes, and a decrease in ejection fraction. However, how exactly changes in sarcomere number translate into changes in myocyte morphology, and how these cellular changes translate into ventricular dilation remains incompletely understood. Here we combined a chronic animal study, continuum growth modeling, and machine learning to quantify correlations between sarcomere dynamics, myocyte morphology, and ventricular dilation. In an eight-week long volume overload study of six pigs, we found that the average sarcomere number increased by +3.8%/week, from 47 to 62, resulting in a myocyte lengthening of +3.3%/week, from 85 to 108 μm , while the sarcomere length and myocyte width remained unchanged. At the same time, the average end diastolic volume increased by +6.0%/week. Using continuum growth modeling and Bayesian inference, we correlated alterations on the subcellular, cellular, and organ scales and found that the serial sarcomere number explained 88% of myocyte lengthening, which, in turn, explained 54% of cardiac dilation. Our results demonstrate that sarcomere number and myocyte length are closely correlated and constitute the major determinants of dilated heart failure. We anticipate our study to be a starting point for more sophisticated multiscale models of heart failure. Our study suggests that altering sarcomere turnover—and with it myocyte morphology and ventricular dimensions—could be a potential therapeutic target to attenuate or reverse the progression of heart failure. **Statement of Significance:** Heart failure is a significant global health problem that affects more than 25 million people worldwide and increases in prevalence as the population ages. Heart failure has been studied excessively at various scales; yet, there is no compelling concept to connect knowledge from the subcellular, cellular, and organ level across the scales. Here we combined a chronic animal study, continuum growth modeling, and machine learning to quantify correlations between sarcomere dynamics, myocyte morphology, and ventricular dilation. We found that the serial sarcomere number explained 88% of myocyte lengthening, which, in turn, explained 54% of cardiac dilation. Our results show that sarcomere number and myocyte length are closely correlated and constitute the major determinants of dilated heart failure. This suggests that altering the sarcomere turnover—and with it myocyte morphology and ventricular dimensions—

could be a potential therapeutic target to attenuate or reverse heart failure. © 2019 Acta Materialia Inc.

Abstract Time series forecasting is essential for informed decision-making in financial markets, but it poses challenges due to the stochastic nature of financial data. Existing forecasting methods, including classical statistical models and machine learning approaches, often struggle with the complexities of multi-series, multi-output predictions. This paper introduces a deep learning framework, N-BEATS-GAN, which combines the strengths of Generative Adversarial Networks (GANs) for risk modelling with the efficient trend predictive capabilities of the deep learning model N-BEATS. The method integrates GAN loss with the Transformation Invariant Loss function with Distance Equilibrium (TILDE-Q) loss to address amplitude and phase distortions in time series forecasting and accelerate model convergence. A dataset derived from MSCI (Morgan Stanley Capital International) Country Index data across ten countries is used for validation. Predictive accuracy is assessed using Mean Absolute Error, Mean Squared Error, Continuous Ranked Probability Score, and a risk quantification method is proposed to evaluate the capacity to capture financial risk. Experimental results demonstrate that N-BEATS-GAN significantly outperforms StockMixer, N-BEATS, DLinear, and PAGAN in both prediction accuracy and risk quantification. N-BEATS-GAN overcomes the limitations of existing models, enabling effective multi-series, multi-output forecasting while accounting for inherent risk in financial time series, highlighting its potential to enhance forecasting and risk assessment in financial markets. © 2025 Elsevier B.V.

Abstract Nanotechnology is a multidisciplinary science that includes scientific and technological activities at molecular and atomic scales (1-100 nm). Scientific principles and new properties can be understood and controlled when working at this scale. Nanotechnology is advancing rapidly due to the great progress achieved in various fields including electronics, mechanics, medicine, cosmetics, food, etc. This increased use of nano-sized materials leads to the release of a substantial amount of nanoparticles into the environment. To date there is a lack of standardized procedures to assess their safety and impact on the environment. Specific toxicological studies as well as characterization and quantification of nanoparticles are required to establish regulations to control field application of nanoscale materials. A classification of nanoparticles and the techniques employed in their characterization, separation, and quantification are summarized and described in this review. A global perspective on nanoparticle exposure and environmental effect is also discussed. © 2014 The Royal Society of Chemistry.

Abstract Nanoplastics are increasingly recognized as emerging stressors that impair photosynthesis in photosynthetic organisms, and their co-occurrence with environmental pollutants can further intensify phytotoxic effects. To address the fragmented understanding of these combined impacts, we integrated a meta-analysis of 1067 experimental observations with explainable machine learning to quantify how nanoplastics and co-pollutants jointly influence photosynthetic processes. The results showed predominantly negative effects across light reactions and rubisco enzyme activity, with organism species, nanoplastics dose, size, and exposure duration identified as major determinants of photosynthetic inhibition. High-sensitivity indicators of photosynthetic stress were identified, and corn emerged as a particularly sensitive organism. By linking physicochemical properties and exposure conditions to quantitative photosynthetic outcomes, this study provides a clearer and more accessible framework for predicting phytotoxicity and supports improved ecological risk assessment and management strategies. © 2026 Elsevier B.V.

NC 2 E: boosting few-shot learning with novel class center estimation

Item Type Journal Article

Author Z. Wu

Author C. Shen

Author E. Luo

Author L. Wang

Abstract Accurate class distribution estimation is expected to solve the problem of the poor generalization ability that exists in few-shot learning models due to data shortages. However, the reliability of class distributions estimates based on limited samples and knowledge is questionable, especially for similar classes. We find that the distribution calibration method is inaccurate in estimating similar classes due to limited knowledge being reused through double-validation experiments. To address this issue, we propose a novel class center estimation (NC2E) method, which consists of a two-stage center estimation (TCE) algorithm and a class centroid estimation (CCE) algorithm. The class centers estimated by TCE in two stages are closer to the truth,

and its superiority is demonstrated by error theory. CCE searches for the centroid of the base class iteratively and is used as the basis for the novel class calibration. Sufficient simulation samples are generated based on the estimated class distribution to augment the training data. The experimental results show that, compared with the distribution calibration method, the proposed method achieves an approximately 1% performance improvement on the miniImageNet and CUB datasets; an approximately 1.45% performance improvement for similar class classification; and an approximately 6.06% performance improvement for non-similar class classification. © 2022, The Author(s), under exclusive licence to Springer-Verlag London Ltd., part of Springer Nature.

Network intrusion detection with cascading classification

Item Type Conference Paper

Author S. Marcek

Author M. Drozda

Editor Al-Dabass D.

Editor Sauli Z.

Editor Zakaria Z.

Abstract The KDD99 network intrusion contest and the related intrusion data sets attracted increased attention of the research community. The success rate of contest participants was evaluated in terms of the obtained classification cost. The classification cost of the contest winner was 0.2331, the best approach prior to our work carries the classification cost of 0.2224. We show that a simple approach based on cascading classification leads to the classification cost of 0.2079. Cascading classification is in our case done by applying 2-nearest-neighbor classification. The samples which could not be predicted with 2-nearest-neighbor classification (4-6%) are further classified with a clustering approach with class priority. This clustering approach when applied in isolation under performs other approaches. However, when applied in cascading classification, it can take advantage of the reduced number of samples. We argue that cascading classification is a viable alternative in scenarios where less complex machine learning approaches are favorable, for example due to possible performance degradation in resource constrained devices such as mobile phones, embedded systems or sensors. © 2014 IEEE.

Network quantification despite biased labels

Item Type Conference Paper

Author L. Tang

Author H. Gao

Abstract The increasing availability of participatory web and social media presents enormous opportunities to study human relations and collective behaviors. Many applications involving decision making want to obtain certain generalized properties about the population in a network, such as the proportion of actors given a category, instead of the category of individuals. While data mining and machine learning researchers have developed many methods for link-based classification or relational learning, most are optimized to classify individual nodes in a network. In order to accurately estimate the prevalence of one class in a network, some quantification method has to be used. In this work, two kinds of approaches are presented: quantification based on classification or quantification based on link analysis. Extensive experiments are conducted on several representative network data, with interesting findings reported concerning efficacy and robustness of different quantification methods, providing insights to further quantify the ebb and flow of online collective behaviors at macro-level. © 2010 ACM.

Network Security Evaluation and Optimal Active Defense based on Attack and Defense Game Model

Item Type Conference Paper**Author** F. Li

Abstract With the rapid development of network technology, information spreads rapidly through the network. High-speed wide area network and broadband metropolitan area network have been widely used in enterprise communications, promoting the improvement of enterprise information level in modern society, and enhancing the market competitiveness of enterprises. However, it is worth noting that while Internet technology and the Internet are widely used, the activities of viruses and hackers are increasingly rampant, and various new network attacks and viruses emerge in an endless stream, bringing unprecedented security risks to network security. The target of attackers is to penetrate the network and steal valuable data. The goal of the defender is to prevent attackers from intruding into the network. Attacks can be divided into two types: reconnaissance and violent attack. Reconnaissance is when an attacker tries to find information about the target, while a violent attack attempts all possible passwords or key combinations until a valid password or password is found. Violent attacks are more likely to succeed against poorly protected systems because they do not require time to test each password or key combination. In order to evaluate the network information system security and active defense, the network defense graph model, the classification of attack and defense strategies and the cost quantification method, the network attack and defense game model and the optimal active defense selection algorithm based on the above models are proposed. Finally, a typical network example is used to analyze the application of the above models and algorithms in network security evaluation and optimal active defense. The analysis results show that the proposed models and methods are feasible and effective. © 2023 IEEE.

Abstract Neuroinflammation is a hallmark of numerous neurodegenerative, psychiatric, and chronic pain disorders and can be assessed in vivo with 18 kDa translocator protein (TSPO) positron emission tomography (PET). However, conventional quantification methods of TSPO PET are limited and often overlook the spatial relationships between regional signals. The application of network-based approaches to TSPO PET imaging may provide a novel framework to capture disease-specific neuroinflammatory patterns. To address this question, here we developed a data-driven, network-based approach to generate individual brain-wide TSPO PET matrices, employing Euclidean distance to quantify inter-regional pharmacokinetics similarity. We applied this approach to a large multicenter dataset of 528 PET scans utilizing three different TSPO tracers ([11C]-PBR28, [18F]-DPA714, [11C]-PK11195), including healthy controls and patients with different diseases such as multiple sclerosis, traumatic brain injury, schizophrenia, depression, and chronic low back pain. Statistical modelling and machine learning classifiers were applied to evaluate the impact of experimental and biological factors on TSPO similarity patterns and to investigate their potential for capturing disease-specific signatures. TSPO similarity patterns demonstrated high biological specificity and reproducibility, with strong test–retest correlations (mean Spearman’s $\rho = 0.84$). Average precision of disease classification exceeded chance performance by 23–89% across conditions and was driven by condition-specific regional hubs whose topological distributions closely mirrored disease pathophysiology. This specificity was further supported by minimal overlap in feature importance values across conditions. Altogether, our findings show that network-based analysis of human TSPO PET data can detect disease-specific neuroinflammatory signatures. Such methodologies underscore the biological significance of TSPO PET and enhance its translational value, supporting precision medicine strategies for neuroinflammatory disorders. © The Author(s) 2026.

Neural minimax classifiers

Item Type Conference Paper
Author R. Alaiz-Rodríguez
Author J. Cid-Sueiro
Editor Dorronsoro J.R.
Editor Dorronsoro J.R.

Abstract Many supervised learning algorithms are based on the assumption that the training data set reflects the underlying statistical model of the real data. However, this stationarity assumption may be partially violated in practice: for instance, if the cost of collecting data is class dependent, the class priors of the training data set may be different from that of the test set. A robust solution to this problem is selecting the classifier that minimize the error probability under the worst case conditions. This is known as the minimax strategy. In this paper we propose a mechanism to train a neural network in order to estimate the minimax classifier that is robust to changes in the class priors. This procedure is illustrated on a softmax-based neural network, although it can be applied to other structures. Several experimental results show the advantages of the proposed methods with respect to other approaches. © Springer-Verlag Berlin Heidelberg 2002.

Abstract Objectives: In a previous study using the averaged coherence technique to study interactions between medial/limbic and lateral/neocortical regions, we observed that epileptogenic networks in temporal lobe epilepsy seizures (TLES) could be divided into 4 subtypes, i.e. medial (M), medial-lateral (ML), lateral-medial (LM), and lateral (L). In the ML and LM subtypes, medial structures and the anterior temporal neocortex are co-activated at the onset of seizures. However, using this approach, we were unable to determine the direction of coupling and may have overlooked non-linear variations in interdependency. The purpose of the present study using non-linear regression for analysis of stereoelectroencephalographic (SEEG) signal pairs

was to measure the degree and direction of coupling between medial and neocortical areas during TLES in patients with the M, ML, and LM subtypes. Methods: Eighteen patients with drug-resistant TLEs who underwent SEEG recording were studied. We used a non-linear correlation method as a measure of the degree and the direction of coupling on SEEG signal pairs. Patients with pure lateral TLEs were not studied. We analyzed the functional coupling between 3 regions of the temporal lobe: the anterior temporal neocortex, the amygdala, and the anterior hippocampus. A physiological model of EEG generation was used to validate the non-linear quantification method and assess its applicability to real SEEG signals. Results: Results are first based on a physiological model of EEG data in which both degree and direction of coupling are explicitly represented, thus allowing construction of the neural systems inside which causality relationships are controlled and generation of multichannel EEG signals from these systems. These signals provide an objective way of studying the performance of non-linear regression analysis on real signals. In medial networks (10 patients), the ictal discharge is limited to the medial limbic structures and may propagate secondarily to the cortex. Quantified results demonstrated no significant coupling between medial and lateral structures at the beginning of the seizures. Conversely, almost constant unidirectional or bidirectional coupling was observed between hippocampus and amygdala. In medial-lateral (5 patients) and lateral-medial (3 patients) networks, the initial ictal discharge includes both limbic and neocortical regions. A rapid 'tonic' discharge is observed over the temporal neocortex at the onset of seizure. Quantitative analysis showed an initial increase in the non-linear correlation coefficient between neocortex and medial structures. Quantification of the coupling direction demonstrated influence of medial over lateral structures (medial-lateral) or of the lateral neocortex over medial structures (lateral-medial). Conclusions: These results confirm the existence of several generic and organized networks involving the medial structures during TLE seizures. © 2001 Elsevier Science Ireland Ltd. Neural stochastic differential equations network as uncertainty quantification method for EEG source localization

Item Type Journal Article

Author R.S. Wabina

Author C. Silpasuwanchai

Abstract EEG source localization remains a challenging problem given the uncertain conductivity values of the volume conductor models (VCMs). As uncertain conductivities vary across people, they may considerably impact the forward and inverse solutions of the EEG, leading to an increase in localization mistakes and misdiagnoses of brain disorders. Calibration of conductivity values using uncertainty quantification (UQ) techniques is a promising approach to reduce localization errors. The widely-known UQ methods involve Bayesian approaches, which utilize prior conductivity values to derive their posterior inference and estimate their optimal calibration. However, these approaches have two significant drawbacks: solving for posterior inference is intractable, and choosing inappropriate priors may lead to increased localization mistakes. This study used the Neural Stochastic Differential equations Network (SDE-Net), a combination of dynamical systems and deep learning techniques that utilizes the Wiener process to minimize conductivity uncertainties in the VCM and improve the inverse problem. Results revealed that SDE-Net generated a lower localization error rate in the inverse problem compared to Bayesian techniques. Future studies may employ new stochastic dynamical systems-based techniques as a UQ technique to address further uncertainties in the EEG Source Localization problem. NeuralUQ: A Comprehensive Library for Uncertainty Quantification in Neural Differential Equations and Operators

Item Type Journal Article

Author Z. Zou

Author X. Meng

Author A.F. Psaros

Author G.E. Karniadakis

Abstract Uncertainty quantification (UQ) in machine learning is currently drawing increasing research interest, driven by the rapid deployment of deep neural networks across different fields, such as computer vision and natural language processing, and by the

need for reliable tools in risk-sensitive applications. Recently, various machine learning models have also been developed to tackle problems in the field of scientific computing with applications to computational science and engineering (CSE). Physics-informed neural networks and deep operator networks are two such models for solving partial differential equations (PDEs) and learning operator mappings, respectively. In this regard, a comprehensive study of UQ methods tailored specifically for scientific machine learning (SciML) models has been provided in [A. F. Psaros et al., J. Comput. Phys., 477 (2023), art. 111902]. Nevertheless, and despite their theoretical merit, implementations of these methods are not straightforward, especially in large-scale CSE applications, hindering their broad adoption in both research and industry settings. In this paper, we present an open-source Python library (<https://github.com/Crunch-UQ4MI>), termed NeuralUQ and accompanied by an educational tutorial, for employing UQ methods for SciML in a convenient and structured manner. The library, designed for both educational and research purposes, supports multiple modern UQ methods and SciML models. It is based on a succinct workflow and facilitates flexible employment and easy extensions by the users. We first present a tutorial of NeuralUQ and subsequently demonstrate its applicability and efficiency in four diverse examples, involving dynamical systems and high-dimensional parametric and time-dependent PDEs. New development for detecting partial discharge using an UHF method and its application to power apparatus in Japan

Item Type Conference Paper

Author M. Nagao

Abstract Insulation diagnosis has been widely applied worldwide in factories and on-site tests to assure the quality of power equipment. Detection of electromagnetic signals in the ultra-high-frequency (UHF) band from a partial discharge (PD) has been widely studied as a highly sensitive insulation diagnostic method for gas-insulated switchgear (GIS). Many of these studies are based on measurements with actual devices and a few systematic theoretical examinations of the basic characteristics of individual sensors and electromagnetic wave propagation [1]. The most frequently authorized method for detecting PD applies the conventional test standard defined by IEC 60270. The conventional method focuses on the kHz band, although the UHF method, which has been recommended by "CIGRE TF15 / 33.03.05" [2], uses wide-frequency components from the MHz to GHz ranges. Besides factory and on-site tests for quality assurance, PD monitoring systems have been developed and the UHF method is also applied by manufacturers. The UHF method, however, raises technical difficulties for quality assurance and product development, i.e., the measurement principle is totally different from IEC 60270; calibration is complicated due to attenuation and reflection; and, TE/TM modes propagate inside GIS. Many research studies using the UHF method are cited in this paper to solve the above difficulties with comparative calibration using the UHF method and IEC 60270 [3-5], sensitivity check of PD-detecting coupler in UHF range [6-9], risk assessment based on estimation of defect size [10-13], and advanced classification and quantification method for PD [14, 15].

New methodology for facilitating food wastage quantification. Identifying gaps and data inconsistencies

Item Type Journal Article

Author H. Barco

Author I. Oribe-Garcia

Author M.V. Vargas-Viedma

Author C.E. Borges

Author C. Martín

Author A. Alonso-Vicario

Abstract The Food and Agriculture Organization of the United Nations estimated that about 1.3 billion tons of food produced for human consumption was lost or wasted globally. Thus, the reduction of the current food loss and waste along the agrifood chain is becoming a priority, both for optimization of resources and reduction waste generation costs. For this purpose, the first step is to quantify the food wastage generation to be able to identify corrective measures. However, in spite of the considerable efforts already undertaken to establish common methodologies to measure the food wastage at different geographical scales, there are still some gaps and inconsistencies. In this regard, the information gathering is labour-intensive because of the different actors involved. The creation of new methodologies and tools capable of automatically identifying these agents would be of great value so as to subsequently apply the more appropriate quantification methodologies. This work aims at providing a new methodology to facilitate this process thanks to the previous identification and classification of the potential food wastage generators. As a result, it provides baseline information for one of the earliest steps of the food wastage quantification process, which is the establishment of the scope of the food wastage inventory. The baseline data needed is taken from the Statistical classification of economic activities in the European Community (NACE), particularly from the most disaggregated level called “classes”. This information has been combined with data from the trading income tax at municipal scale thanks to the use of Geographic

Information Systems (GIS) and the common codes for NACE classes, generating a visual tool for the localization of points with potential of food-wastage generation and their weight of each economic activity over the agrifood chain. The proposed methodology has been implemented for the real case of the municipality of Zamudio (Spain) and it has allowed the identification of the different entities linked with economic activities that are potential generators of food wastage, the weight of each activity over the entire agrifood chain, and the geographical location of these entities in the territory. Furthermore, this methodology was used to compare the nature and number of these activities in another municipality (Karrantza, Spain) and it has also been applied to the entire region of the Basque Country (Spain). © 2018 Elsevier Ltd

New results on diagnosis by fuzzy pattern recognition

Item Type Conference Paper

Author M.S. Bouguelid

Author M.S. Mouchaweh

Author P. Billaudel

Abstract We use the classification method Fuzzy Pattern Matching (FPM) to realize the industrial and medical diagnosis. FPM is marginal, i.e., its global decision is based on the selection of one of the intermediate decisions. Each intermediate decision is based on one attribute. Thus, FPM does not take into account the correlation between attributes. Additionally, FPM considers the shape of classes as convex one. Finally the classes are considered as equi-important by FPM. These drawbacks make FPM unusable for many real world applications. In this paper, we propose improving FPM to solve these drawbacks. Several synthetic and real data sets are used to show the performances of the Improved FPM (IFPM) with respect to classical one as well as to the well known classification method K Nearest Neighbours (KNN). KNN is known to be preferment in the case of data represented by correlated attributes or by classes with different a priori probabilities and non convex shape.

New Trends in Quantitative Nuclear Cardiology Methods

Item Type Journal Article

Author J. Gomez
Author R. Doukky
Author G. Germano
Author P. Slomka

Abstract Purpose of Review: The use of quantitative analysis in single photon emission computed tomography (SPECT) and positron emission tomography (PET) has become an integral part of current clinical practice and plays a crucial role in the detection and risk stratification of coronary artery disease. Emerging technologies, new protocols, and new quantification methods have had a significant impact on the diagnostic performance and prognostic value of nuclear cardiology imaging while reducing the need for clinician oversight. In this review, we aim to describe recent advances in automation and quantitative analysis in nuclear cardiology. Recent Findings: Recent publications have shown that fully automatic processing is feasible, limiting human input to specific cases where aberrancies are detected by the quality control software. Furthermore, there is evidence indicating that fully quantitative analysis of myocardial perfusion imaging is feasible and can achieve at least similar diagnostic accuracy as visual interpretation by an expert clinician. In addition, the use of fully automated quantification in combination with machine learning algorithms can provide incremental diagnostic and prognostic value over the traditional method of expert visual interpretation. Summary: Emerging technologies in nuclear cardiology focus on automation and the use of artificial intelligence as part of the interpretation process. This review highlights the benefits and limitations of these applications and outlines future directions in the field. © 2018, Springer Science+Business Media, LLC, part of Springer Nature.

NLSC: A noise-robust label shift correction framework via three-head training and class-adaptive cleaning

Item Type Journal Article

Author X. Wu

Author R. Fan

Author T. Luo

Author C. Hou

Abstract Label shift occurs when the conditional distributions remain consistent between source and target domains, but the marginal label distributions differ. For instance, during the early stage of the COVID-19 outbreak, the proportion of pneumonia cases compared to common cold cases in hospitals may have been relatively low. This ratio could shift dramatically in later stages of the pandemic, with pneumonia cases becoming predominant, even though the symptomatic presentation of each disease remained consistent. Existing label shift methods typically aim to adapt a classifier's output to match the target domain's label distribution, assuming the source domain has clean labels. However, real-world scenarios often involve label noise in the source domain. For example, during COVID-19's early phase, mild and confusable symptoms frequently led to misdiagnoses of COVID-19 as the common cold, introducing label noise. Such noise compromises the effectiveness of traditional methods, necessitating novel approaches. To address this, we analyze classifier error bounds under label shift correction using noisy source data. Based on this analysis, we propose a Noise-robust Label Shift Correction (NLSC) framework. NLSC employs a Three-Head Architecture Training (THAT) strategy for robust feature learning and a Class-Adaptive Threshold Cleaning (CATC) strategy for source data purification. Extensive experiments confirm that our method outperforms existing state-of-the-art techniques, particularly in real-world scenarios with high source domain noise rates. © 2025 Elsevier Inc.

No-reference image quality assessment of T2-weighted magnetic resonance images in prostate cancer patients

Item Type Conference Paper**Author** S. Masoudi**Author** S. Harmon**Author** S. Mehralivand**Author** N. Lay**Author** U. Bagci**Author** B.J. Wood**Author** P.A. Pinto**Author** P. Choyke**Author** B. Turkbey

Abstract No-reference image quality assessment in magnetic resonance (MR) imaging is a challenging task due to the variable nature of these images and lack of standard quantification methods, which makes the interpretation to be almost always subjective. In this study, we propose an architecture where we: (i) extended the no-reference image quality assessment problem of MRI into a full-reference image quality assessment using unpaired generative adversarial network (GAN) and (ii) employed a weakly supervised trained deep classifier to determine the quality of MR images by comparing each image with its synthetic higher quality reference image. Using this approach, we achieved 11.28% improvement in the accuracy of our MR image quality assessment algorithm on an independent data test with FPR in detecting low quality images, reduced from 13% to 9.6%. © 2021 IEEE.

Node trust prediction framework in mobile Ad Hoc networks

Item Type Conference Paper
Author H. Xia
Author G.-D. Wang
Author Z.-K. Pan
Abstract Trust quantification methods depends on the deployment region, network applications, level of security required. Considering the environment of mobile ad hoc networks, in this study we propose a new trust model. This new model is divided into two parts: trust assessment and trust prediction. The process of node trust assessment is based on node's historical behaviors, in which the trust decision factors include the subjective reputation and indirect reputation. Then utilizing the obtained trust data sequence, we propose an improved dynamic grey-Markov chain prediction measure to predict node's trust for future decision making. In which we eliminates grey bias via using unbiased GM(1,1) model. Moreover, in order to improve anti-jamming performance, we introduce the fuzzy classification method to classify the fuzzy states into some reasonable groups. Experimental results have been conducted to evaluate the effectiveness of the

proposed model. It is proved in theory and practice that the prediction results not only are more reliable but also can help the decision maker with grasping the change tendency of trust and making proper decisions. © 2016 IEEE.

Abstract Mycotoxin contamination by aflatoxin B1 (AFB1) and deoxynivalenol (DON) in maize silage threatens feed safety, requiring rapid, non-destructive monitoring tools. This study developed a visible-light machine vision approach combined with machine learning to quantify AFB1 and DON and classify contamination levels. A total of 210 silage samples were imaged, and 111 RGB-based color and texture features were extracted, followed by correlation analysis and model-based feature selection. Using the 10 selected features, support vector regression (SVR) achieved the best quantitative performance for AFB1 ($R^2 = 0.9945$, $RMSE = 3.18 \mu\text{g}\cdot\text{kg}^{-1}$), while XGBoost performed best for DON ($R^2 = 0.9816$, $RMSE = 45.50 \mu\text{g}\cdot\text{kg}^{-1}$). For classification, random forest and XGBoost correctly identified AFB1 contamination levels with an Accuracy of 90.48%, whereas SVM achieved 97.62% Accuracy for DON. Comparison of correlation-based and model-based feature importance confirmed the complementary value of statistically significant and nonlinearly predictive features. Biological interpretation suggested that color and texture responses may reflect fungal pigmentation/browning and multiscale surface-structure alterations, respectively, with selected texture descriptors changing earlier than color descriptors during aerobic exposure. The proposed low-cost RGB imaging strategy, coupled with multi-feature fusion, offers a promising approach for high-throughput preliminary mycotoxin screening in feed production. © 2026 by the authors.

Abstract Mycelial biocomposites are sustainable alternatives to nonbiodegradable materials in building and packaging. Efficient manufacturing requires accurate, non-destructive quantification of growth over time, yet existing methods are often destructive or imprecise. This study develops and evaluates several non-destructive quantification methods for wood-flour biocomposites by using images to define mycelial density levels, low (no visible growth, removable surface hyphal coverage $< 7.8\%/cm^2$), medium (light growth, $7.8\%–26.7\%/cm^2$), and high (dense coverage, $> 26.7\%/cm^2$), and tracking changes in each level over time. The first method, the manual creation of masks for each growth level, provided rapid but coarse classification, estimating 64.1% high growth after 16 days with 3.5% user variability. An algorithmic masking approach improved detail detection, increasing estimated high-growth coverage to 81.7% but also variability to 9.3%. A fully automated deep-learning model proved fastest and most consistent, yielding 77.8% high-growth coverage and eliminating intra-user variability (0%). The deep-learning method was then applied to assess the effects of substrate supplements, revealing distinct growth patterns for each—differences not captured by traditional methods. These results demonstrate the effectiveness of automated quantification for mycelial biocomposites, enabling reproducible, high-resolution, non-destructive monitoring of growth and providing a foundation for more precise engineering and wider adoption of these materials. © 2025 Wiley Periodicals LLC.

Non-exchangeable Conformal Prediction with Optimal Transport: Tackling Distribution Shifts with Unlabeled Data

Item Type Conference Paper

Author A.H.C. Correia

Author C. Louizos

Abstract Conformal prediction is a distribution-free uncertainty quantification method that has gained popularity in the machine learning community due to its finite-sample guarantees and ease of use. Its most common variant, dubbed split conformal prediction, is also computationally efficient as it boils down to collecting statistics

of the model predictions on some calibration data not yet seen by the model. Nonetheless, these guarantees only hold if the calibration and test data are exchangeable, a condition that is difficult to verify and often violated in practice due to so-called distribution shifts. The literature is rife with methods to mitigate the loss in coverage in this non-exchangeable setting, but these methods require some prior information on the type of distribution shift to be expected at test time. In this work, we study this problem via a new perspective, through the lens of optimal transport, and show that it is possible to estimate the loss in coverage and mitigate arbitrary distribution shifts, offering a principled and broadly applicable solution. © 2025 Neural information processing systems foundation. Non-intrusive soil carbon content quantification methods using machine learning algorithms: A comparison of microwave and millimeter wave radar sensors

Item Type Journal Article

Author D. An

Author Y. Chen

Abstract Agricultural and forestry biomass can be converted to biochar through pyrolysis gasification, making it a significant carbon source for soil. Applying biochar to soil is a carbon-negative process that helps combat climate change, sustain soil biodiversity, and regulate water cycling. However, quantifying soil carbon content conventionally is time-consuming, labor-intensive, imprecise, and expensive, making it difficult to accurately measure in-field soil carbon's effect on storage water and nutrients. To address this challenge, this paper for the first time, reports on extensive lab tests

demonstrating non-intrusive methods for sensing soil carbon and related smart biochar applications, such as differentiating between biochar types from various biomass feedstock species, monitoring soil moisture, and biochar water retention capacity using portable microwave and millimeter wave sensors, and machine learning. These methods can be scaled up by deploying the sensor in-field on a mobility platform, either ground or aerial. The paper provides details on the materials, methods, machine learning workflow, and results of our investigations. The significance of this work lays the foundation for assessing carbon-negative technology applications, such as soil carbon content accounting. We validated our quantification method using supervised machine learning algorithms by collecting real soil mixed with known biochar contents in the field. The results show that the millimeter wave sensor achieves high sensing accuracy (up to 100%) with proper classifiers selected and outperforms the microwave sensor by approximately 10%–15% accuracy in sensing soil carbon content. © 2023 The Authors

Non-stationary data sequence classification using online class priors estimation

Item Type Journal Article

Author C. Yang

Author J. Zhou

Abstract Online classification is important for real time data sequence classification. Its most challenging problem is that the class priors may vary for non-stationary data sequences. Most of the current online-data-sequence-classification algorithms assume that the class labels of some new-arrived data samples are known and retrain the classifier accordingly. Unfortunately, such assumption is often violated in real applications. But if we were able to estimate the class priors on the test data sequence accurately, we could adjust the classifier without retraining it while preserving a reasonable accuracy. There has been some work on the class priors estimation to classify static data sets using the offline iterative EM algorithm, which has been proved to be quite effective to adjust the classifier. Inspired by the offline iterative EM algorithm for static data sets, in this paper, we propose an online incremental EM algorithm to estimate the class priors along the data sequence. The classifier is adjusted accordingly to keep pace with the varying distribution. The proposed online algorithm is more computationally efficient because it scans the sequence only once. Experimental results show that the proposed algorithm indeed performs better than the conventional offline iterative EM algorithm when the class priors are non-stationary. © 2008 Elsevier Ltd. Abstract Carotenoids, a class of naturally occurring pigments ubiquitously distributed across plant and animal kingdoms, serve vital biological functions in photoprotection and antioxidant defense mechanisms. Within plant systems, these compounds critically modulate photosynthetic efficiency under drought stress conditions. While carotenoid content fluctuations offer a reliable biomarker for evaluating plant drought responses, conventional chemical quantification methods remain labor-intensive and unsuitable for large-scale agricultural monitoring. This investigation employs hyperspectral imaging technology (operating in the 859–1705 nm spectral range) to acquire spectral signatures from *Chrysanthemum × morifolium* (Ramat.) Hemsl. samples, subsequently applying five spectral preprocessing techniques to optimize data quality. Three feature selection algorithms (Successive Projections Algorithm, Max-Relevance Min-Redundancy, and Competitive Adaptive Reweighted Sampling) were employed to identify diagnostically significant wavelengths, while three regression models (Random Forest Regression, Partial Least Squares Regression, and Gradient Boosting Machine) were constructed for carotenoid prediction. SHapley Additive exPlanations analysis was performed to assess the interpretability and relative contributions of different feature selection approaches. Experimental results demonstrate that the SPA-Random Forest Regression hybrid model achieved optimal prediction performance (RC = 0.9545, RMSEC = 0.0096, RP = 0.9228, RSMEP = 0.0134). Notably, the Random Forest Regression algorithm attained 99.03% classification accuracy in drought stress discrimination. This methodology establishes the viability of integrating hyperspectral imaging with machine learning as a non-destructive analytical framework for simultaneous carotenoid quantification and plant drought stress assessment. © 2026 Elsevier B.V.

Abstract Fibrotic diseases affect multiple organs and are associated with morbidity and mortality. To examine organ-specific and shared biologic mechanisms that underlie fibrosis in different organs, we developed machine learning models to quantify T1 time, a marker of interstitial fibrosis, in the liver, pancreas, heart and kidney among 43,881 UK Biobank participants who underwent magnetic resonance imaging. In phenome-wide association analyses, we demonstrate the association of increased organ-specific T1 time, reflecting increased interstitial fibrosis, with prevalent diseases across multiple organ systems. In genome-wide association analyses, we identified 27, 18, 11 and 10 independent genetic loci associated with liver, pancreas, myocardial and renal cortex T1 time, respectively. There was a modest genetic

correlation between the examined organs. Several loci overlapped across the examined organs implicating genes involved in a myriad of biologic pathways including metal ion transport (SLC39A8, HFE and TMPRSS6), glucose metabolism (PCK2), blood group antigens (ABO and FUT2), immune function (BANK1 and PPP3CA), inflammation (NFKB1) and mitosis (CENPE). Finally, we found that an increasing number of organs with T1 time falling in the top quintile was associated with increased mortality in the population. Individuals with a high burden of fibrosis in ≥ 3 organs had a 3-fold increase in mortality compared to those with a low burden of fibrosis across all examined organs in multivariable-adjusted analysis (hazard ratio = 3.31, 95% confidence interval 1.77–6.19; $P = 1.78 \times 10^{-4}$). By leveraging machine learning to quantify T1 time across multiple organs at scale, we uncovered new organ-specific and shared biologic pathways underlying fibrosis that may provide therapeutic targets. © The Author(s), under exclusive licence to Springer Nature America, Inc. 2024.

Normative Alignment of Recommender Systems via Internal Label Shift

Item Type Conference Paper

Author J. Kruse

Author K. Lindschow

Author M.R. Andersen

Author R. Shimizu

Author J. McAuley

Author P.-A. Mattei

Author J. Frellsen

Abstract Recommender systems optimized solely for user engagement often fail to meet broader normative objectives such as fairness, diversity, or editorial values. We introduce NAILS (Normative Alignment of recommender systems via Internal Label Shift), a simple and scalable method for aligning recommendation outputs with target distributions over item-level attributes (e.g., categories). NAILS modifies the user-conditional item distribution to induce a specified marginal distribution over attributes, leveraging existing user-item preferences without retraining the model. To achieve this, we recast the problem as a form of label shift applied internally within a hierarchical classification framework. Adopting a stakeholder-centric perspective, NAILS enables alignment with global normative goals. Empirically, we show that NAILS consistently improves attribute-level alignment with minimal impact on user engagement, providing a practical mechanism for value-driven recommendation. Novel algorithm for classification of medical images

Item Type Conference Paper

Author B. Bhushan

Author M. Juneja

Abstract Content-based image retrieval (CBIR) methods in medical image databases have been designed to support specific tasks, such as retrieval of medical images. These methods cannot be transferred to other medical applications since different imaging modalities require different types of processing. To enable content-based queries in diverse collections of medical images, the retrieval system must be familiar with the current Image class prior to the query processing. Further, almost all of them deal with the DICOM imaging format. In this paper a novel algorithm based on energy information obtained from wavelet transform for the classification of medical images according to their modalities is described. For this two types of wavelets have been used and have been shown that energy obtained in either case is quite distinct for each of the body part. This technique can be successfully applied to different image formats. The results are shown for JPEG imaging format. © 2010 American Institute of Physics.

Novel Algorithm to Detect, Classify, and Count Mussel Larvae in Seawater Samples Using Computer Vision

Item Type Journal Article

Author P. Orgeira-Crespo

Author C. Gabín-Sánchez

Author F. Aguado-Agelet

Author G. Rey-González

Abstract Featured Application: Automatic detection, classification, and accounting of mussel larvae in their different stages of growth using computer vision. The European Union's mussel production industry is dependent on obtaining mussel larvae as seed for cultivation, a process traditionally monitored through labor-intensive manual sampling and microscopic counting prone to human error and time-consuming procedures. To address these challenges, our research presents a computer vision-based methodology for accurately identifying, classifying, and quantifying mussel larvae individuals across various developmental stages from microscopic images of water samples. Utilizing a neural network architecture derived from the YOLO method, our approach integrates convolutional, pooling, and fully connected layers to automate detection, classification, and accounting tasks. Through training with manually labeled samples and employing data augmentation techniques, we established a robust framework capable of processing diverse larval specimens effectively. Our research not only streamlines mussel larvae monitoring processes but also underscores the potential of computer vision techniques to enhance efficiency and accuracy in aquaculture industries. © 2024 by the authors.

Novel approach for quantification for severity estimation of blight diseases on leaves of tomato plant

Item Type Journal Article

Author A.S. Charak

Author A. Sinha

Author T. Jain

Abstract This study uses digital image processing and machine learning to quantify the infection patterns on tomato leaves due to blight diseases. Quantification, also known as severity measurement, is a technique to determine how much a leaf is diseased by calculating a numeric value. This value could be a fraction representing how much the diseased region is present on the leaf compared to the entire leaf region, or it can be a percentage value too. There are two main approaches to measuring disease severity; the first technique involves visual estimation using references like standard area diagrams. The second approach involves taking a digital image of the leaf, separating the diseased regions from the healthy regions, and then calculating the area of those two regions. The approach we took is similar. We first took the digital image and segmented the diseased and healthy regions. For quantification, we calculated the ratio of total pixels representing the diseased region to the total number of pixels representing the leaf. While finding ways to improve the accuracy of the segmentation algorithm, we also discovered our segmentation technique which automatically segments the diseased regions of the leaves from the healthy areas using k-means clustering. The clustering-segmentation algorithm did give good results for the sample images to which it was applied. The main thing about the clustering-segmentation algorithm is that it tends to be automatic compared to some

of the semi-automatic segmentation approaches that have been discovered till now. We could reproduce the validated quantification results as other authors achieved in the recent work, which also validated our methodology. © 2022 John Wiley & Sons Ltd.

Novel fluorescence spectroscopy method coupled with N-PLS-R and PLS-DA models for the quantification of cannabinoids and the classification of cannabis cultivars

Item Type Journal Article

Author M. Birenboim

Author D. Kenigsbuch

Author J.A. Shimshoni

Abstract Introduction: Cannabis sativa L. inflorescences are rich in secondary metabolites, particularly cannabinoids. The most common techniques for elucidating cannabinoid composition are expensive technologies, such as high-pressure liquid chromatography (HPLC). Objectives: We aimed to develop and evaluate the

performance of a novel fluorescence spectroscopy-based method coupled with N-way partial least squares regression (N-PLS-R) and partial least squares discriminant analysis (PLS-DA) models to replace the expensive chromatographic methods for preharvest cannabinoid quantification. Methodology: Fresh medicinal cannabis inflorescences were collected and ethanol extracts were prepared. Their excitation–emission spectra were measured using fluorescence spectroscopy and their cannabinoid contents were determined by HPLC-PDA. Subsequently, N-PLS-R and PLS-DA models were applied to the excitation–emission matrices (EEMs) for cannabinoid concentration prediction and cultivar classification, respectively. Results: The N-PLS-R model was based on a set of EEMs ($n = 82$) and provided good to excellent quantification of (–)- Δ^9 -trans-tetrahydrocannabinolic acid, cannabidiolic acid, cannabigerolic acid, cannabichromenic acid, and (–)- Δ^9 -trans-tetrahydrocannabinol (R^2_{CV} and $R^2_{pred} > 0.75$; $RPD > 2.3$ and $RPIQ > 3.5$; $RMSECV/RMSEC$ ratio < 1.4). The PLS-DA model enabled a clear distinction between the four major classes studied (sensitivity, specificity, and accuracy of the prediction sets were all ≥ 0.9). Conclusions: The fluorescence spectral region (excitation 220–400 nm, emission 280–550 nm) harbors sufficient information for accurate prediction of cannabinoid contents and accurate classification using a relatively small data set. © 2023 John Wiley & Sons Ltd.

NRU-HSE at SemEval-2016 task 4: Comparative analysis of two iterative methods using quantification library

Item Type Conference Paper

Author N. Karpov

Author A. Porshnev

Author K. Rudakov

Abstract In many areas, such as social science, politics or market research, people need to track sentiment and their changes over time. For sentiment analysis in this field it is more important to correctly estimate proportions of each sentiment expressed in the set of documents (quantification task) than to accurately estimate sentiment of a particular document (classification). Basically, our study was aimed to analyze the effectiveness of two iterative quantification techniques and to compare their effectiveness with baseline methods. All the techniques are evaluated using a set of synthesized data and the SemEval-2016 Task4 dataset. We made the quantification methods from this paper available as a Python open source library. The results of comparison and possible limitations of the quantification techniques are discussed. © 2016 Association for Computational

Nuclear magnetic resonance analysis of extra virgin olive oil: classification through secoiridoids

Item Type Journal Article

Author C.G. Tsiafoulis

Author C. Liaggou

Author A. Garoufis

Author P. Magiatis

Author I.G. Roussis

Abstract BACKGROUND: Extra virgin olive oil (EVOO), a natural product with a multidisciplinary role, has been and is continuing to be studied from several points of view. Among them, its chemical analysis is of major importance and several methods have been used. Nuclear magnetic resonance (NMR) spectroscopy has inherent

advantages, among them monitoring the chemical constituents without the need for a separation technique and without, for instance, possible carry-over effects. Additionally, several magnetic resonance spectroscopic techniques can provide a novel powered insight into the nature and properties of a sample under study. Moreover, -omics procedure can reveal new information and can lead to the classification of populations under study. The main objective of the present work was the possible classification of the EVOO samples based on their aldehyde content using a proposed unreferenced ¹H-NMR spectroscopic quantification method combined with a metabolomic approach. Moreover, the study of the impact of such elevated aldehyde content on several spectra regions of importance in the proton NMR spectra led to the proposal of a possible new isomer indicator. RESULTS: Univariate analysis of 12 EVOO samples showed that oleacein, oleocanthal, elenolic acid, hydroxytyrosol/hydroxytyrosol derivatives and tyrosol/tyrosol derivatives strongly differentiated two classes of EVOO: OEH (for high aldehyde EVOO content) and OE (for non-high aldehyde content). Moreover, we pointed out the 'impact' of such elevated secoiridoid and derivatives content, through their moieties' units, on a range of several resonances of the ¹H-NMR spectrum. The metabolomic approach demonstrated the classification of EVOO samples based on their secoiridoid and derivatives content. Multivariate analysis showed a strong influence on the discrimination of the EVOO classes based on the protons resonating at the aldehyde region of the ¹H-NMR spectrum; the aldehyde protons corresponding to 5S,4R-ligstrodiol and 5S,4R-oleuropeindiol, oleacein, oleocanthal, elenolic acid, p-HPEA-EA, 3,4-DHPEA-EA, 5S,4R- and 5S,4S-ligstrodiol and the proton corresponding to a new compound were reported for the first time. This isomer compound, reported for the first time, could serve as a possible indicator for EVOO classification. CONCLUSIONS: An unreferenced quantification method was proposed and EVOO samples were classified into two classes: OEH and OE, according to their aldehyde content, gaining thus probably higher nutrient and possible pharmacological value. Moreover, we point out the 'impact' of such elevated aldehyde content on several spectral regions of the ¹H spectrum. Finally, a new compound was detected in the OEH samples and is reported for the first time. This compound could possibly be an indicator. © 2023 The Authors. Author L. Chen

Abstract Earth's fragile high-altitude ecosystems are facing challenges from nutrient pollution, where data scarcity and complex topography create significant knowledge gaps. This study conducted the first large-scale survey and established a comprehensive inventory of human activities in the Qinghai Lake basin, the largest lake on the Qinghai-Tibet Plateau. We developed a hybrid framework that integrated detailed surveys, process-based modeling, and interpretable machine learning to quantify nitrogen and phosphorus fluxes despite data gaps. Notably, ungauged basins around the lake contribute substantially (34% of phosphorus and 21% of nitrogen) to the lake load, highlighting a serious underestimation of a blind spot in global monitoring networks. Contemporary anthropogenic emissions contributed only 41.12% of TN flux and 45.22% of TP flux. Further machine learning analysis indicates that non-direct human factors (runoff, climate, and geographical conditions) have a dominant influence on nutrient movement. These findings provide a replicable framework for data-poor regions and call for shifting management paradigms from anthropocentric to ecosystem-based approaches across high-altitude areas. © 2026 Elsevier Ltd

Abstract Accurate and real-time monitoring of grapevine freezing tolerance is crucial for the sustainability of the grape industry in cool climate viticultural regions. However, on-site data are limited due to the complexity of measurement. Current prediction models underperform under diverse climate conditions, which limits the large-scale deployment of these methods. We combined grapevine freezing tolerance data from multiple regions in North America and generated a predictive model based on hourly temperature-derived features and cultivar features using AutoGluon, an automated machine learning engine. Feature importance was quantified by AutoGluon and SHAP (SHapley Additive exPlanations) value. The final model was evaluated and compared with previous models for its performance under different climate conditions. The final model achieved an overall 1.36°C root-mean-square error during model testing and outperformed two previous models using three test cultivars at all testing regions. Two feature importance quantification methods identified five shared essential features. Detailed analysis of the features indicates that the model has adequately extracted some biological mechanisms during training. The final model, named NYUS.2, was deployed along with two previous models as an R shiny-based application in the 2022–23 dormancy season, enabling large-scale and real-time simulation of grapevine freezing tolerance in North America for the first time. © The Author(s) 2024. OASIS: Open-world Adaptive Self-supervised and Imbalanced-aware System

Item Type Conference Paper

Author M. Kim

Author M. Joe

Author M. Kwon

Abstract The expansion of machine learning into dynamic environments presents challenges in handling open-world problems where label shift, covariate shift, and unknown classes emerge concurrently. Post-training methods have been explored to address these challenges, adapting models to newly emerging data. However, these methods struggle when the initial pre-training is performed on class-imbalanced datasets, limiting generalization to minority classes. To address this, we propose OASIS, an Open-world Adaptive Self-supervised and Imbalanced-aware System. OASIS consists of two learning phases: pre-training and post-training. The pre-training phase aims to improve the classification performance of samples near class boundaries via a novel borderline sample refinement step. Notably, the borderline sample refinement step critically improves the robustness of the decision boundary in the representation space. Through this robustness of the pre-trained model, OASIS generates reliable pseudo-labels, adapting the model against open-world problems in the post-training phase. Extensive experiments demonstrate that our method significantly outperforms state-of-the-art post-training techniques in both accuracy and efficiency across diverse open-world scenarios. © 2025 Copyright held by the owner/author(s).

Object recognition using proportion-based prior information: Application to fisheries acoustics

Item Type Journal Article

Author R. Lefort

Author R. Fablet

Author J.-M. Boucher

Abstract This paper addresses the inference of probabilistic classification models using weakly supervised learning. The main contribution of this work is the development of learning methods for training datasets consisting of groups of objects with known relative class priors. This can be regarded as a generalization of the situation addressed by Bishop and Ulusoy (2005), where training information is given as the presence or absence of object classes in each set. Generative and discriminative classification methods are conceived and compared for weakly supervised learning, as well as a non-linear version of the probabilistic discriminative models. The considered models are evaluated on standard datasets and an application to fisheries acoustics is reported. The proposed proportion-based training is demonstrated to outperform model learning based on presence/absence information and the potential of the non-linear discriminative model is shown. © 2010 Elsevier B.V. Objective class definitions using correlation of similarities between remotely sensed and environmental data

Item Type Journal Article

Author S. Andrefouet

Author M. Claereboudt

Abstract This letter presents a natural approach for selecting a subset of environmental variables to define classes prior to mapping them efficiently using remotely sensed data. The procedure is based on correlation calculations between a set of 'environmental' similarity matrices and an 'image' similarity matrix. The correlation is a modified Spearman rank correlation. Using a SPOT-HRV image and seven environmental variables, an application in a coral reef environment showed that only three environmental variables are relevant to defining classes prior to mapping. © 2000 Taylor & Francis Group, LLC.

Abstract Deep neural networks (DNNs) have been widely applied for detecting COVID-19 in medical images. Existing studies mainly apply transfer learning and other data representation strategies to generate accurate point estimates. The generalization power of these networks is always questionable due to being developed using small datasets and failing to report their predictive confidence. Quantifying uncertainties associated with DNN predictions is a prerequisite for their trusted deployment in medical settings. Here we apply and evaluate three uncertainty quantification techniques for COVID-19 detection using chest X-Ray (CXR) images. The novel concept of uncertainty confusion matrix is proposed and new performance metrics for the objective evaluation of uncertainty estimates are introduced. Through comprehensive experiments, it is shown that networks pertained on CXR images outperform networks pretrained on natural image datasets such as ImageNet. Qualitatively and quantitatively evaluations also reveal that the predictive uncertainty estimates are statistically higher for erroneous predictions than correct predictions. Accordingly, uncertainty quantification methods are capable of flagging risky

predictions with high uncertainty estimates. We also observe that ensemble methods more reliably capture uncertainties during the inference. DNN-based solutions for COVID-19 detection have been mainly proposed without any principled mechanism for risk mitigation. Previous studies have mainly focused on generating single-valued predictions using pretrained DNNs. In this paper, we comprehensively apply and comparatively evaluate three uncertainty quantification techniques for COVID-19 detection using chest X-Ray images. The novel concept of uncertainty confusion matrix is proposed and new performance metrics for the objective evaluation of uncertainty estimates are introduced for the first time. Using these new uncertainty performance metrics, we quantitatively demonstrate when we could trust DNN predictions for COVID-19 detection from chest X-rays. It is important to note the proposed novel uncertainty evaluation metrics are generic and could be applied for evaluation of probabilistic forecasts in all classification problems. © 2022, The Author(s).

Obukhov Length Estimation From Spaceborne Radars

Item Type Journal Article

Author O. O'Driscoll

Author A. Mouche

Author B. Chapron

Author M. Kleinherenbrink

Author P. López-Dekker

Abstract Two air-sea interaction quantification methods are employed on synthetic aperture radar (SAR) scenes containing atmospheric-turbulence signatures. Quantification performance is assessed on Obukhov length L , an atmospheric surface-layer stability metric. The first method correlates spectral energy at specific turbulence-spectrum wavelengths directly to L . Improved results are obtained from the second method, which relies on a machine-learning algorithm trained on a wider array of SAR-derived parameters. When applied on scenes containing convective signatures, the second method is able to predict approximately 80% of observed variance with respect to validation. Estimated wind speed provides the bulk of predictive power while parameters related to the kilometer-scale distribution of spectral energy contribute to a significant reduction in prediction errors, enabling the methodology to be applied on a scene-by-scene basis. Differences between these physically based estimates and parameterized numerical models may guide the latter's improvement. © 2023. The Authors.

Abstract One of the key obstacles in traditional deep learning is the reduction in model transparency caused by increasingly intricate model functions, which can lead to problems such as overfitting and excessive confidence in predictions. With the advent of quantum machine learning offering possible advances in computational power and latent space complexity, we notice the same opaque behavior. Despite significant research in classical contexts, there has been little advancement in addressing the black-box nature of quantum machine learning. Consequently, we approach this gap by building upon existing work in classical uncertainty quantification and initial explorations in quantum Bayesian modeling to theoretically develop and empirically evaluate techniques to map classical uncertainty quantification methods to the quantum machine learning domain. Our findings emphasize the necessity of leveraging classical insights into uncertainty quantification to include uncertainty awareness in the process of designing new quantum machine learning models. © 2025 IEEE.

ON INFORMATION GAIN, KULLBACK-LEIBLER DIVERGENCE, ENTROPY PRODUCTION AND THE INVOLUTION KERNEL

Item Type Journal Article

Author A.O. Lopes

Author J.K. Mengue

Abstract It is well known that in Information Theory and Machine Learning the Kullback-Leibler divergence, which extends the concept of Shannon entropy, plays a fundamental role. Given an a priori probability kernel $\hat{v}$ and a probability π on the measurable space $X \times Y$ we consider an appropriate definition of entropy of π relative to $\hat{v}$, which is based on previous works. Using this concept of entropy we obtain a natural definition of information gain for general measurable spaces which coincides with the mutual information given from the K-L divergence in the case $\hat{v}$ is identified with a probability v on X . This will be used to extend the meaning of specific information gain and dynamical entropy production to the model of thermodynamic formalism for symbolic dynamics over a compact alphabet (TFCA model). Via the concepts of involution kernel and dual potential, one can ask if a given potential is symmetric - the relevant information is available in the potential. In the affirmative case, its corresponding equilibrium state has zero entropy production. © 2022 American Institute of Mathematical Sciences. All rights reserved.

On Intra-page and Inter-page Semantic Analysis of Web Pages

Item Type Conference Paper

Author J. Wang

Author J. Wang

Author G. Wu

Author H. Tsuda

Editor Ji D.H.

Editor Lua K.T.

Abstract To make real Web information more machine processable, this paper presents a new approach to intra-page and inter-page semantic analysis of Web pages. Our approach consists of Web pages structure analysis and semantic clustering for intra-page semantic analysis, and machine learning based link semantic analysis for inter-page analysis. Based on the automatic repetitive patterns discovery in structure level and clustering in semantic level, we explore the intra-page semantic structure of Web pages and extend the processing unit from the whole page to a finer granularity, i.e., semantic information blocks within pages. After observing the various hyperlinks, we synthesize the Web inter-page semantic and

define an information organizing oriented hyperlink semantic category. Considering the presentation of the hyperlink carrier and intra-page semantic structure, we propose corresponding feature selection and quantification methods, and then exploit the C4.5 decision-tree method to classify hyperlink semantic type and analyze the inter-page semantic structure. In our experiments, the results suggest that our approach is feasible for machine processing. © 2003 Chinese and Oriental Languages Information Processing Society. All right reserved.

On learning multcategory classification with sample queries

Item Type Journal Article

Author J. Ratsaby

Abstract Consider the pattern recognition problem of learning multcategory classification from a labeled sample, for instance, the problem of learning character recognition where a category corresponds to an alphanumeric letter. The classical theory of pattern recognition assumes labeled examples appear according to the unknown underlying pattern-class conditional probability distributions where the pattern classes are picked randomly according to their a priori probabilities. In this paper we pose the following question: Can the learning accuracy be improved if labeled examples are independently randomly drawn according to the underlying class conditional probability distributions but the pattern classes are chosen not necessarily

according to their a priori probabilities? We answer this in the affirmative by showing that there exists a tuning of the sub-sample proportions which minimizes a loss criterion. The tuning is relative to the intrinsic complexity of the Bayes-classifier. As this complexity depends on the underlying probability distributions which are assumed to be unknown, we provide an algorithm which learns the proportions in an on-line manner utilizing sample querying which asymptotically minimizes the criterion. In practice, this algorithm may be used to boost the performance of existing learning classification algorithms by apportioning better sub-sample proportions.

On Machine Learning-Based Techniques for Future Sustainable and Resilient Energy Systems

Item Type Journal Article

Author J. Wang

Author P. Pinson

Author S. Chatzivasileiadis

Author M. Panteli

Author G. Strbac

Author V. Terzija

Abstract Permanently increasing penetration of converter-interfaced generation and renewable energy sources (RESs) makes modern electrical power systems more vulnerable to low probability and high impact events, such as extreme weather, which could lead to severe contingencies, even blackouts. These contingencies can be further propagated to neighboring energy systems over coupling components/technologies and consequently negatively influence the entire multi-energy system (MES) (such as gas, heating and electricity) operation and its resilience. In recent years, machine learning-based techniques (MLBTs) have been intensively applied to solve various power system problems, including system planning, or security and reliability assessment. This paper aims to review MES resilience quantification methods and the application of MLBTs to assess the resilience level of future sustainable energy systems. The open research questions are identified and discussed, whereas the future research directions are identified. © 2010-2012 IEEE.

On naive Bayesian fusion of dependent classifiers

Item Type Journal Article

Author H. Altınçay

Abstract In classifier combination, the relative values of a posteriori probabilities assigned to different hypotheses are more important than the accuracy of their estimates. Because of this, the independence requirement in naive Bayesian fusion should be examined from combined accuracy point of view. In this study, it is investigated whether there is a set of dependent classifiers which provides a better combined accuracy than independent classifiers when naive Bayesian fusion is used. For this purpose, two classes and three classifiers case is initially considered where the pattern classes are not equally probable. Taking into account the increased complexity in formulations, equal a priori probabilities are considered in the general case where N classes and K classifiers are used. The analysis carried out has shown that the combination of dependent classifiers using naive Bayesian fusion may provide much better combined accuracies compared to independent classifiers. © 2005 Elsevier B.V. Author S. Major

Author G. Dawson

Author D.E. Carlson

Editor Chaudhuri K.

Editor Sugiyama M.

Abstract Discrepancy between training and testing do-mains is a fundamental problem in the gener-alization of machine learning techniques. Re-cently, several approaches have been proposed to learn domain invariant feature representa-tions through adversarial deep learning. How-ever, label shift, where the percentage of data in each class is different between domains, has received less attention. Label shift naturally arises in many contexts, especially in behav-ioral studies where the behaviors are freely chosen. In this work, we propose a method called Domain Adversarial nets for Target Shift (DATS) to address label shift while learn-ing a domain invariant representation. This is accomplished by using distribution match-ing to estimate label proportions in a blind test set. We extend this framework to handle multiple domains by developing a scheme to upweight source domains most similar to the target domain. Empirical results show that this framework performs well under large la-bel shift in synthetic and real experiments, demonstrating the practical importance. © 2019 by the author(s).

On the characterization of continuous fibres fracture by quantifying acoustic emission and acousto-ultrasonics waveforms

Item Type Journal Article

Author Y.Z. Pappas

Author A. Kontsos

Author T.H. Loutas

Author V. Kostopoulos

Abstract The aim of the present work is the classification of the characteristics of elastic waves, which are generated by fibre failures during quasi-static tensile fibre bundle tests and captured by the use of acoustic emission (AE) method. In addition, elastic waves generated out of the fibre bundle gauge length and propagated through the bundle at different stages of the loading process using an acousto-ultrasonic (AU) technique are also classified. To this target, a large number of tests were conducted on organic, ceramic and carbon fibre bundles according to DIN 53942. An in-house developed analysis and quantification methodology of the captured AE and AU waveforms is proposed in order to identify the frequency content of the fibre failure event, to characterize the medium of propagation and to investigate the effect of the acquisition system on the monitored signals. In fact, the application of the proposed analysis on the results of the conducted mechanical tests leads to the development of a useful database, concerning the ranges of AE features and the representative sets of frequency values that correspond to fibre fracture. Furthermore, the proposed database offers valuable knowledge for the role of material parameters, such as fibre structure and properties, on the characteristics of the recorded waveforms, constituting in this way a valuable tool that enables a better understanding of elastic waves initiation and propagation through continuous fibres. © 2003 Published by Elsevier Ltd.

On the damage behaviour in dual-phase DP800 steel deformed in single and combined strain paths

Item Type Journal Article
Author M.A. Wollenweber

Author S. Korte-Kerzel

Abstract Ductile damage in dual-phase steels deteriorates the mechanical properties, resulting in a lowered crashworthiness and a shorter life-time under cyclic loading. However, most works focus on the observation of damage under simple strain paths, even though work pieces are often subjected to combined strain paths during forming. In this work, we set out to characterise the damage behaviour for a DP800 steel subjected to combinations of tensile and bending loads. To this end, we use an automated approach based on machine learning to quantify damage in high-resolution SEM panoramic images, coupled with finite element modelling to determine the stress state, and high-throughput nanoindentation to determine the strain hardening behaviour. We find a strong connection between loading direction and damage formation in both steps of the forming process. By focussing on different possible combinations of positive and negative triaxiality, we show that the combination of two deformation modes with positive triaxiality leads to a promotion of damage formation. A negative triaxiality applied after a positive triaxiality leads to void closure, reducing the number of damage sites and total void area. Importantly, deformation with negative triaxiality carried out before deformation with positive triaxiality inhibits damage nucleation and growth due to strain hardening. © 2023 The Authors

On the Impact of Perceptual Compression on Deep Learning

Item Type Conference Paper

Author G. Friedland

Author R. Jia

Author J. Wang

Author B. Li

Author N. Mundhenk

Abstract This paper proposes a fundamental answer to a frequently asked question in multimedia evaluation and data set creation: Do artifacts from perceptual compression contribute to error in the machine learning process and if so, how much? Our approach to the problem is an information reinterpretation of the Helmholtz free energy formula to explain the relationship between content and noise when using sensors (such as cameras or microphones) to capture multimedia data. The reinterpretation guides a bit-measurement of the noise contained in images, audio, and video by combining a classifier with perceptual compression, such as JPEG or MP3. Our experiments on CIFAR-10, ImageNet, and CSAIL Places as well as Fraunhofer's IDMT-SMT-Audio-Effects dataset indicate that, at the right quality level, perceptual compression is actually not harmful but contributes to a significant reduction of complexity of the machine learning process. That is, our noise quantification method can be used to speed up the training of deep learning classifiers significantly while maintaining, or sometimes even improving, overall classification accuracy. © 2020 IEEE.

Author M. Sugiyama

Abstract Empirical risk minimization (ERM), with proper loss function and regularization, is the common practice of supervised classification. In this paper, we study training arbitrary (from linear to deep) binary classifier from only unlabeled (U) data by ERM. We prove that it is impossible to estimate the risk of an arbitrary binary classifier in an unbiased manner given a single set of U data, but it becomes possible given two sets of U data with different class priors. These two facts answer a fundamental question-what the minimal supervision is for training any binary classifier from only U data. Following these findings, we propose an ERM-based learning method from two sets of U data, and then prove it is consistent. Experiments demonstrate the proposed method could train deep models and outperform state-of-the-art methods for learning from two sets of U data. © 7th International Conference on Learning Representations, ICLR 2019. On the surplus accuracy of data-driven energy quantification methods in the residential sector

Item Type Journal Article

Author L. Wederhake

Author S. Wenninger

Author C. Wiethe

Author G. Fridgen

Abstract Increasing trust in energy performance certificates (EPCs) and drawing meaningful conclusions requires a robust and accurate determination of building energy performance (BEP). However, existing and by law prescribed engineering methods, relying on physical principles, are under debate for being error-prone in practice and ultimately inaccurate. Research has heralded data-driven methods, mostly machine learning algorithms, to be promising alternatives: various studies compare engineering and data-driven methods with a clear advantage for data-driven methods in terms of prediction accuracy for BEP. While previous studies only investigated the prediction accuracy for BEP, it yet remains unclear which reasons and cause–effect relationships lead to the surplus prediction accuracy of data-driven methods. In this study, we develop and discuss a theory on how data collection, the type of auditor, the energy quantification method, and its accuracy relate to one another. First, we introduce cause–effect relationships for quantifying BEP method-agnostically and investigate the influence of several design parameters, such as the expertise of the auditor issuing the EPC, to develop our theory. Second, we evaluate and discuss our theory with literature. We find that data-driven methods positively influence cause–effect relationships, compensating for deficits due to auditors’ lack of expertise, leading to high prediction accuracy. We provide recommendations for future research and practice to enable the informed use of data-driven methods. © 2022, The Author(s).

On the Use of m-Probability-Estimation and Imprecise Probabilities in the Naïve Bayes Classifier

Item Type Journal Article
Author J.G. Castellano
Author S. Moral-García
Author C.J. Mantas
Author J. Abellán
Abstract Within the field of supervised classification, the naïve Bayes (NB) classifier is a very simple and fast classification method that obtains good results, being even comparable with much more complex models. It has been proved that the NB model is strongly dependent on the estimation of conditional probabilities. In the literature, it had been shown that the classical and Laplace estimations of probabilities have some drawbacks and it was proposed a NB model that takes into account the a priori probabilities in order to estimate the conditional probabilities, which was called m-probability-estimation. With a very scarce experimentation, this approximation based on m-probability-estimation demonstrated to provide better results than NB with classical and Laplace estimations of probabilities. In this research, a new naïve Bayes variation is proposed, which is based on the m-probability-estimation version and takes into account imprecise probabilities in order to calculate the a priori probabilities. An exhaustive experimental research is carried out, with a large number of data sets and different levels of class noise. From this experimentation, we can conclude that the proposed NB model and the m-probability-estimation approach

provide better results than NB with classical and Laplace estimation of probabilities. It will be also shown that the proposed NB implies an improvement over the m-probability-estimation model, especially when there is some class noise. © 2020 World Scientific Publishing Company.

On the value of uncertainty quantification in deep learning based breast cancer molecular subtype classification

Item Type Journal Article

Author G.A.D. Tchokponhoue

Author A. Idri

Abstract Cancer is still a major global health issue and one of the leading causes of death globally. Despite significant progress in the field of machine learning (ML) and deep learning (DL) in the medical field and especially in cancer research, uncertainty quantification has been largely under-investigated, resulting in the development of decision systems with questionable reliability and confidence, which are essential for

effective integration and adoption in a clinical context. In this study, we evaluate and discuss five uncertainty quantification (UQ) methods: Single Deterministic, Monte Carlo Dropout (MCD), Bayesian Neural Network based on Variational Inference (BNN), Deep Ensemble (DE), and Bootstrap Ensemble (BG) for the identification of breast cancer molecular subtype using a deep neural network (DNN). These empirical evaluations were based, in addition to the classical classification performance criteria such as accuracy, recall, precision and f1 score, on other advanced criteria related to sensibility, interpretability, robustness, and out-of-distribution (OOD) detection. Moreover, we introduce and evaluate new algorithms for synthetic OOD data generation, crucial for assessing the reliability of quantified uncertainties. Results indicated that Ensemble-based UQ methods generally provided more robust uncertainty estimates and performed best in terms of sensitivity. Stochastic methods, on the other hand, achieved superior calibration, with Bayesian Neural Networks in particular demonstrating strong robustness to adversarial attacks, an attribute that may enhance the generalization capacity of classifiers. Overall, we found that uncertainty estimates not only provide reliable confidence measures but also enhance the transparency of model predictions, supporting safer clinical deployment. © 2025 Elsevier B.V.

On Truthing Issues in Supervised Classification

Item Type Journal Article

Author J.K. Su

Abstract Ideal supervised classification assumes known correct labels, but various truthing issues can arise in practice: noisy labels; multiple, conflicting labels for a sample; missing labels; and different labeler combinations for different samples. Previous work introduced a noisy-label model, which views the observed noisy labels as random variables conditioned on the unobserved correct labels. It has mainly focused on estimating the conditional distribution of the noisy labels and the class prior, as well as estimating the correct labels or training with noisy labels. In a complementary manner, given the conditional distribution and class prior, we apply estimation theory to classifier testing, training, and comparison of different combinations of labelers. First, for binary classification, we construct a testing model and derive approximate marginal posteriors for accuracy, precision, recall, probability of false alarm, and F-score, and joint posteriors for ROC and precision-recall analysis. We propose minimum mean-square error (MMSE) testing, which employs empirical Bayes algorithms to estimate the testing-model parameters and then computes optimal point estimates and credible regions for the metrics. We extend the approach to multi-class classification to obtain optimal estimates of accuracy and individual confusion-matrix elements. Second, we present a unified view of training that covers probabilistic (i.e., discriminative or generative) and non-probabilistic models. For the former, we adjust maximum-likelihood or maximum a posteriori training for truthing issues; for the latter, we propose MMSE training, which minimizes the MMSE estimate of the empirical risk. We also describe suboptimal training that is compatible with existing infrastructure. Third, we observe that mutual information lets one express any labeler combination as an equivalent single labeler, implying that multiple mediocre labelers can be as informative as, or more informative than, a single expert labeler. Experiments demonstrate the effectiveness of the methods and confirm the implication. © 2023 Massachusetts Institute of Technology.

On using the modularity of recurrence network communities to detect change-point behaviour

Item Type Journal Article

Author D.M. Walker

Author A. Zaitouny

Author D.C. Corrêa

Abstract The behaviour of a dynamical system can be examined from time series using the technique of recurrence plots through visualization and quantification methods. One such method is the quadrant scan in which a recurrence plot of a time series is converted into a second time series whose local maxima can be identified and interpreted as possible transitions in dynamic behaviour. A recurrence plot can also be represented as a complex network. A quadrant scan can similarly be thought of as a partition of the network vertices into two communities. Here, we argue that different dynamic behavioural regimes can be realized as network communities and the quality of such partitions can be assessed using modularity. Thereby, community modularity can be used as an alternative to the quadrant scan. We investigate this correspondence with respect to two promising arenas for quadrant scan uptake, namely, concept drift detection from machine learning and tipping point or failure and damage monitoring in system maintenance. We also examine two additional data sets to highlight the potential of the methods. These are a geophysical time series of earth tremor data and a physiological time series of an electrocardiogram. © 2021 Elsevier Ltd

Abstract Objective: The aim of the present study was to carry out a systematic research on bitterness quantification to provide a reference for scholars and pharmaceutical developers to carry out drug taste masking research. Significance: The bitterness of medications poses a significant concern for clinicians and patients. Scientifically measuring the intensity of drug bitterness is pivotal for enhancing drug palatability and broadening their clinical utility. Methods: The current study was carried out by conducting a systematic literature review that identified relevant papers from indexed databases. Numerous studies and research are cited and quoted in this article to summarize the features, strengths, and applicability of quantitative bitterness assessment methods. Results: In our research, we systematically outlined the classification and key advancements in quantitative research methods for assessing

drug bitterness, including in vivo quantification techniques such as traditional human taste panel methods, as well as in vitro quantification methods such as electronic tongue analysis. It focused on the quantitative methods and difficulties of bitterness of natural drugs with complex system characteristics and their difficulties in quantification, and proposes possible future research directions. Conclusion: The quantitative methods of bitterness were summarized, which laid an important foundation for the construction of a comprehensive bitterness quantification standard system and the formulation of accurate, efficient and rich taste masking strategies. Abstract This paper proposes one-class quantification, a new Machine Learning task. Quantification estimates the class distribution of an unlabeled sample of instances. Similarly to one-class classification, we assume that only a sample of examples of a single class is available for learning, and we are interested in counting the cases of such class in a test set. We formulate, for the first time, one-class quantification methods and assess them in a comprehensible open-set evaluation. In an open-set problem, several “subclasses” represent the negative class, and we cannot assume to have enough observations for all of them at training time. Therefore, new classes may appear after deployment, making this a challenging setup for existing quantification methods. We show that our proposals are simple and more accurate than the state-of-the-art in quantification. Finally, the approaches are very efficient, fitting batch and stream applications. One-step Label Shift Adaptation via Robust Weight Estimation

Item Type Conference Paper

Author R. Fan

Author X. Ouyang

Author T. Luo

Author L. Zhang

Author C. Hou

Editor Kwok J.

Abstract Label shift is a prevalent phenomenon encountered in open environments, characterized by a notable discrepancy in the label distributions between the source (training) and target (test) domains, whereas the conditional distributions given the labels remain invariant. Existing label shift methods adopt a two-step strategy: initially computing the importance weight and subsequently utilizing it to calibrate the target outputs. However, this conventional strategy overlooks the intricate interplay between output adjustment and weight estimation. In this paper, we introduce a novel approach termed as One-step Label Shift Adaptation (OLSA). Our methodology jointly learns the predictive model and the corresponding weights through a bi-level optimization framework, with the objective of minimizing an upper bound on the target risk. To enhance the robustness of our proposed model, we incorporate a debiasing term into the upper-level classifier training and devise a regularization term for the lower-level weight estimation. Furthermore, we present theoretical analyses about the generalization bounds, offering guarantees for the model's performance. Extensive experimental results substantiate the efficacy of our proposal. © 2025 International Joint Conferences on Artificial Intelligence. All rights reserved.

Abstract Background: Axial spondyloarthritis (axSpA) can potentially progress to ankylosing spondylitis, and diagnostic delay may lead to irreversible structural damage. Although sacroiliac joint magnetic resonance imaging (MRI) can detect bone marrow edema (BME) for early diagnosis, the complex etiologies and reliance on expert interpretation impede efficient identification in chronic low back pain populations.

Therefore, we developed an artificial intelligence (AI) system that integrates MRI analysis and automates report generation to facilitate the detection of active sacroiliitis and BME quantification. **Methods:** This retrospective study analyzed 691 patients (540 with axSpA and 151 with non-spondyloarthritis) from the Chinese People's Liberation Army General Hospital (2011–2023). Data were split into training and testing cohorts (4:1 ratio), with five-fold cross-validation applied to the training set. The system comprises four modules: (1) image preprocessing (intensity normalization), (2) coarse-to-fine 3D U-Net-based quadrant segmentation, (3) ResNet18-driven edema recognition (depth/intensity classification), and (4) diagnostic report generation using the QWEN large language model. **Results:** Among 691 patients (335 active sacroiliitis-positive and 356 negative), the AI system achieved Spondyloarthritis Research Consortium of Canada (SPARCC) scores of (15.12 ± 10.73) vs. (0.88 ± 1.13) in positive versus negative groups, respectively. The quadrant segmentation module achieved DICE similarity coefficients above 0.7 on the training, validation, and testing datasets. The edema inflammation, depth, and intensity classifiers exhibited good performance on the testing dataset, with balanced accuracies of 77.54%, 76.26%, and 80.91%, and area under the curve values of 0.85, 0.87, and 0.92, respectively. The intraclass correlation coefficient between SPARCC scores by our system and those by rheumatologists was 0.84 on the testing dataset. At the patient-level, our system achieved 90.81% sensitivity for diagnosis of active sacroiliitis on the testing dataset. **Conclusion:** The developed automated system enhances axSpA diagnostic efficiency by automating the identification of active sacroiliitis and enabling quantitative assessment of BME. © 2025

Abstract Machine learning models often encounter distribution shifts when deployed in the real world. In this paper, we focus on adaptation to label distribution shift in the online setting, where the test-time label distribution is continually changing and the model must dynamically adapt to it without observing the true label. Leveraging a novel analysis, we show that the lack of true label does not hinder estimation of the expected test loss, which enables the reduction of online label shift adaptation to conventional online learning. Informed by this observation, we propose adaptation algorithms inspired by classical online learning techniques such as Follow The Leader (FTL) and Online Gradient Descent (OGD) and derive their regret bounds. We empirically verify our findings under both simulated and real world label distribution shifts and show that OGD is

particularly effective and robust to a variety of challenging label shift scenarios.

Online Continual Learning via Logit Adjusted Softmax

Item Type Journal Article

Abstract Online continual learning is a challenging problem where models must learn from a non-stationary data stream while avoiding catastrophic forgetting. Inter-class imbalance during training has been identified as a major cause of forgetting, leading to model prediction bias towards recently learned classes. In this paper, we

theoretically analyze that inter-class imbalance is entirely attributed to imbalanced class-priors, and the function learned from intra-class intrinsic distributions is the optimal classifier that minimizes the class-balanced error. To that end, we present that a simple adjustment of model logits during training can effectively resist prior class bias and pursue the corresponding optimum. Our proposed method, Logit Adjusted Softmax, can mitigate the impact of inter-class imbalance not only in class-incremental but also in realistic scenarios that sum up class and domain incremental learning, with little additional computational cost. We evaluate our approach on various benchmarks and demonstrate significant performance improvements compared to prior arts. For example, our approach improves the best baseline by 4.6% on CIFAR10. Abstract This paper addresses the prevalent issue of label shift in an online setting with missing labels, where data distributions change over time and obtaining timely labels is challenging. While existing methods primarily focus on adjusting or updating the final layer of a pre-trained classifier, we explore the untapped potential of enhancing feature representations using unlabeled data at test-time. Our novel method, Online Label Shift adaptation with Online Feature Updates (OLS-OFU), leverages self-supervised learning to refine the feature extraction process, thereby improving the prediction model. By carefully designing the algorithm, theoretically OLS-OFU maintains the similar online regret convergence to the results in the literature while taking the improved features into account. Empirically, it achieves substantial improvements over existing methods, which is as significant as the gains existing methods have over the baseline (i.e., without distribution shift adaptations). © 2024 Neural information processing systems foundation. Abstract This paper focuses on supervised and unsupervised online label shift, where the class marginals $Q(y)$ varies but the class-conditionals $Q(x|y)$ remain invariant. In the unsupervised setting, our goal is to adapt a learner, trained on some offline labeled data, to changing label distributions given unlabeled online data. In the supervised setting, we must both learn a classifier and adapt to the dynamically evolving class marginals given only labeled online data. We develop novel algorithms that reduce the adaptation problem to online regression and guarantee optimal dynamic regret without any prior knowledge of the extent of drift in the label distribution. Our solution is based on bootstrapping the estimates of online regression oracles that track the drifting proportions. Experiments across numerous simulated and real-world online label shift scenarios demonstrate the superior performance of our proposed approaches, often achieving 1-3% improvement in accuracy while being sample and computationally efficient. Online optimization methods for the quantification problem

Item Type Conference Paper**Author** P. Kar**Author** S. Li**Author** H. Narasimhan**Author** S. Chawla**Author** F. Sebastiani

Abstract The estimation of class prevalence, i.e., of the fraction of a population that belongs to a certain class, is an important task in data analytics, and finds applications in many domains such as the social sciences, market research, epidemiology, and others. For example, in sentiment analysis the goal is often not to estimate whether a specific text conveys a positive or a negative sentiment, but rather to estimate the overall distribution of positive and negative sentiments, e.g., in a certain time frame. A popular way of performing the above task, often dubbed quantification, is to use supervised learning in order to train a prevalence estimator from labeled data. In the literature there are several performance metrics for measuring the success of such prevalence estimators. In this paper we propose the first online stochastic algorithms for directly optimizing these quantification-specific performance measures. We also provide algorithms that optimize hybrid performance measures that seek to balance quantification and classification performance. Our algorithms present a significant advancement in the theory of multivariate optimization; we show, via a rigorous theoretical analysis, that they exhibit optimal convergence. We also report extensive experiments on benchmark and real data sets which demonstrate that our methods significantly outperform existing optimization techniques used for these performance measures. © 2016 ACM.

Open Set Label Shift with Test Time Out-of-Distribution Reference

Item Type Conference Paper**Author** C. Ye**Author** R. Tsuchida**Author** L. Petersson**Author** N. Barnes

Abstract Open set label shift (OSLS) occurs when label distributions change from a source to a target distribution, and the target distribution has an additional out-of-distribution (OOD) class. In this work, we build estimators for both source and target open set label distributions using a source domain in-distribution (ID) classifier and an ID/OOD classifier. With reasonable assumptions on the ID/OOD classifier, the estimators are assembled into a sequence of three stages: 1) an estimate of the source label distribution of the OOD class, 2) an EM algorithm for Maximum Likelihood estimates (MLE) of the target label distribution, and 3) an estimate of the target label distribution of OOD class under relaxed assumptions on the OOD classifier. The sampling errors of estimates in 1) and 3) are quantified with a concentration inequality. The estimation result allows us to correct the ID classifier trained on the source distribution to the target distribution without retraining. Experiments on a variety of open set label shift settings demonstrate the effectiveness of our model. Our code is available at <https://github.com/ChangkunYe/OpenSetLabelShift>. © 2025 IEEE.

Open-Set Hypothesis Transfer with Semantic Consistency

Item Type Journal Article

Author Z. Feng

Author C. Xu

Author D. Tao

Abstract Unsupervised open-set domain adaptation (UODA) is a realistic problem where unlabeled target data contain unknown classes. Prior methods rely on the coexistence of both source and target domain data to perform domain alignment, which greatly limits their applications when source domain data are restricted due to privacy concerns. In this paper we address the challenging hypothesis transfer setting for UODA, where data from source domain are no longer available during adaptation on target domain. Specifically, we propose to use pseudo-labels and a novel consistency regularization on target data, where using conventional formulations fails in this open-set setting. Firstly, our method discovers confident predictions on target domain and performs classification with pseudo-labels. Then we enforce the model to output consistent and definite predictions on semantically similar transformed inputs, discovering all latent class semantics. As a result, unlabeled data can be classified into discriminative classes coincided with either source classes or unknown classes. We theoretically prove that under perfect semantic transformation, the proposed objective that enforces consistency can recover the information of true labels in

prediction. Experimental results show that our model outperforms state-of-the-art methods on UODA benchmarks. © 1992-2012 IEEE.

OpenSlot: Mixed Open-Set Recognition With Object-Centric Learning

Item Type Journal Article

Author X. Yin

Author F. Pan

Author G. An

Author Y. Huo

Author Z. Xie

Author S.-E. Yoon

Abstract Existing open-set recognition (OSR) studies typically assume that each image contains only one class label, with the unknown test set (negative) having a disjoint label space from the known test set (positive), a scenario referred to as full-label shift. This paper introduces the mixed OSR problem, where test images contain multiple

class semantics, with both known and unknown classes co-occurring in the negatives, leading to a more complex super-label shift that better reflects real-world scenarios. To tackle this challenge, we propose the OpenSlot framework, based on object-centric learning, which uses slot features to represent diverse class semantics and generate class predictions. The proposed anti-noise slot (ANS) technique helps mitigate the impact of noise (invalid or background) slots during classification training, addressing the semantic misalignment between class predictions and ground truth. We evaluate OpenSlot on both mixed and conventional OSR benchmarks. Without elaborate designs, our method not only excels existing approaches in detecting super-label shifts across OSR tasks, but also achieves state-of-the-art performance on conventional benchmarks. Meanwhile, OpenSlot can localize class objects without using bounding boxes during training, demonstrating competitive performance in open-set object detection and potential for generalization. © 1999-2012 IEEE.

Opportunistic Osteoporosis Screening from Routine Knee Radiographs Using a Multi-Stage CNN Framework with External Validation

Item Type Journal Article

Author N. Sinnathakorn

Author C. Fahpinyo

Author W. Chalamjiak

Author S. Suantai

Abstract Background/Objectives: Osteoporosis is a major public health concern associated with increased fracture risk and reduced quality of life if not detected at an early stage. Automated analysis of knee X-ray images using artificial intelligence has shown promising potential for opportunistic osteoporosis screening. This study aims to develop and evaluate a multi-stage deep learning and machine learning framework for osteoporosis classification, with particular emphasis on external validation, calibration drift, and cross-domain generalization performance. Methods: Knee X-ray images were categorized into three classes: Normal, Osteopenia, and Osteoporosis. Deep features were extracted using pretrained convolutional neural networks, including ResNet18, EfficientNetB0, and DenseNet121. The extracted features were subsequently classified using multiple machine learning models, including Neural Network, Efficient Linear, Support Vector Machine, and Naive Bayes classifiers. Two data augmentation strategies were investigated: targeted minority-class augmentation and full $3\times$ dataset expansion with class balancing. Model performance was evaluated using accuracy, precision, recall, F1-score, and AUC on internal validation, independent test sets, and external validation datasets. Additional analyses included reliability calibration assessment, isotonic recalibration, and class-prior boosting with cross-validated threshold optimization to address external domain shift. Results: EfficientNetB0 and DenseNet121 consistently outperformed ResNet18 across most evaluation metrics. Under the balanced augmentation strategy, EfficientNetB0 combined with Efficient Linear demonstrated strong and stable performance, while DenseNet121 paired with a Neural Network achieved the highest overall classification performance. External validation revealed a substantial discrepancy between AUC and threshold-based metrics, indicating the presence of calibration drift and class-prior mismatch across imaging domains. Reliability analysis showed severe probability collapse in the Osteopenia class during external testing. Post-hoc recalibration improved probability reliability, while class-prior boosting substantially increased Osteopenia sensitivity and improved balanced accuracy and macro F1-score under external validation conditions. Conclusions: The proposed framework demonstrates the feasibility of combining pretrained CNN-based deep feature extraction with machine learning classifiers for osteoporosis classification from knee X-ray images. The findings further highlight that maintaining model performance under external testing conditions may require not only strong feature extraction capability but also adaptive recalibration and deployment-aware threshold optimization to address calibration drift and cross-domain variability. While the results are encouraging, the present study should be considered a proof-of-concept investigation. Although the framework was evaluated using an independent public external dataset, further validation using larger and more diverse multi-center clinical cohorts is necessary to establish generalizability and clinical utility before routine clinical implementation can be considered. © 2026 by the authors.

Optimal Bayesian classifier for land cover classification using Landsat TM data

Item Type Conference Paper
Author Yuanxin Zhu
Author Yunxin Zhao
Author Kannappan Palaniappan
Author Xiaobo Zhou
Author Xinhua Zhuang
Abstract An optimal Bayesian classifier using mixture distribution class models with joint learning of loss and prior probability functions is proposed for automatic land cover classification. The probability distribution for each land cover class is more realistically modeled as a population of Gaussian mixture densities. A novel two-stage learning algorithm is proposed to learn the Gaussian mixture model parameters for each land cover class and the optimal Bayesian classifier that minimizes the loss due to misclassification. In the first stage, the Gaussian

mixture model parameters for a given land cover class is learned using the Expectation-Maximization algorithm. The Minimum Description Length principle is used to automatically determine the number of Gaussian components required in the mixture model without overfitting. In the second stage, the loss functions and the a priori probabilities are jointly learned using a multiclass perceptron algorithm. Preliminary results indicate that modeling the multispectral, multitemporal remotely sensed radiance data for land cover using a Gaussian mixture model is superior to using unimodal Gaussian distributions. Higher classification accuracies for eight typical land cover categories over one full Landsat scene in central Missouri are demonstrated.

Optimal classification and generalized prevalence estimates for diagnostic settings with more than two classes

Item Type Journal Article

Author R.A. Luke

Author A.J. Kearsley

Author P.N. Patrone

Abstract An accurate multiclass classification strategy is crucial to interpreting antibody tests. However, traditional methods based on confidence intervals or receiver operating characteristics lack clear extensions to settings with more than two classes. We address this problem by developing a multiclass classification based on probabilistic

modeling and optimal decision theory that minimizes the convex combination of false classification rates. The classification process is challenging when the relative fraction of the population in each class, or generalized prevalence, is unknown. Thus, we also develop a method for estimating the generalized prevalence of test data that is independent of classification of the test data. We validate our approach on serological data with severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) naïve, previously infected, and vaccinated classes. Synthetic data are used to demonstrate that (i) prevalence estimates are unbiased and converge to true values and (ii) our procedure applies to arbitrary measurement dimensions. In contrast to the binary problem, the multiclass setting offers wide-reaching utility as the most general framework and provides new insight into prevalence estimation best practices. © 2023

OPTIMAL TRANSPORT MEETS NOISY LABEL ROBUST LOSS AND
MIXUP REGULARIZATION FOR DOMAIN ADAPTATION

Item Type Conference Paper

Author K. Fatras

Author H. Naganuma

Author I. Mitliagkas

Editor Chandar S.

Editor Pascanu R.

Editor Precup D.

Abstract It is common in computer vision to be confronted with domain shift: images which have the same class but different acquisition conditions. In domain adaptation (DA), one wants to classify unlabeled target images using source labeled images. Unfortunately, deep neural networks trained on a source training set perform poorly on target images which do not belong to the training domain. One strategy to improve these performances is to align the source and target image distributions in an embedded space using optimal transport (OT). However OT can cause negative transfer, i.e. aligning samples with different labels, which leads to overfitting especially in the presence of label shift between domains. In this work, we mitigate negative alignment by explaining it as a noisy label assignment to target images. We then mitigate its effect by appropriate regularization. We propose to couple the MixUp regularization (Zhang et al., 2018a) with a loss that is robust to noisy labels in order to improve domain adaptation performance. We show in an extensive ablation study that a combination of the two techniques is critical to achieve improved performance. Finally, we evaluate our method, called MIXUNBOT, on several benchmarks and real-world DA problems. © Proceedings of Machine Learning Research 2022.

Optimal Trunk-Reservation by Policy Learning

Item Type Conference Paper

Author A. Massaro

Author F. De Pellegrini

Author L. Maggi

Abstract In the framework of queuing theory with multiclass jobs, trunk-reservation is an admission control technique to handle job class priority in an online fashion, and serve as many high priority jobs as possible. This is achieved by rejecting jobs with sufficiently low priority when the buffer space becomes a scarce resource, i.e., when the queue may soon overflow. Mathematically, the objective is to maximize the long-term reward of the admitted jobs, where each job is assigned a reward which is monotonic with respect to the priority class it belongs to. In this paper we study online learning of optimal trunk-reservation policies when the system parameters, i.e., class arrival rates and service time, are unknown. Starting from a Markov Decision Process (MDP) formulation, we leverage the stairway structure of the optimal policy to define Integer Gradient Ascent (IGA), a reinforcement learning (RL) algorithm based on policy-gradient methods, specifically tailored to the mathematical properties of the problem at hand. We provide theoretical results on the convergence properties of IGA. Extensive numerical experiments characterize its behavior and confirm that it outperforms standard RL techniques in terms of convergence rate. © 2019 IEEE.

Optimization of Spare Parts Varieties Based on Stochastic DEA Model

Item Type Journal Article

Author M. Wen

Author T. Zu

Author M. Guo

Author R. Kang

Author Y. Yang

Abstract Accurate inventory management starts with the scientific and rational classification of numerous varieties of spare parts. This paper presents a stochastic data envelopment analysis (DEA) model to address the problem of optimization of spares varieties under uncertainty. An index system is proposed in terms of product life-cycle process, which contains five design indexes, four operation indexes and five support indexes. Then, the quantification method of the index system is briefly discussed in preparation for mathematical calculation. A stochastic spares optimization model (SSOM) is proposed based on stochastic DEA with the constraints of 14 factors of the index system. The SSOM could be converted into equivalent deterministic models by probability theory, which overcomes the difficulty in solving non-linear programming. A numerical example is given to illustrate the proposed method in terms of ability to provide reasonable inventory management policies. © 2013 IEEE.

Optimization of the area under the ROC curve

Item Type Conference Paper

Author C.L. Castro

Author A.P. Braga

Abstract In this paper, we propose a new binary classification algorithm (AUCtron), based on gradient descent learning, that directly optimizes AUC (Area Under the ROC Curve). We compare it with a linear classifier and with AUCsplit proposed by [5]. The AUCtron algorithm implicitly considers class prior probabilities in the decision criteria. Our results demonstrated that AUC is a sensitive enough metric that when used in small and imbalanced data sets may lead to a better separation. © 2008 IEEE.

Optimized Distributed Automatic Modulation Classification in Wireless Sensor Networks Using Information Theoretic Measures

Item Type Journal Article

Author S. Hakimi

Author G. Abed Hodtani

Abstract Automatic modulation classification of digital signals is essential for intelligent communication systems. This paper addresses the distributed classification of digital amplitude-phase modulated signals in a system of multiple sensors, which observe the unknown signal corrupted with the additive white Gaussian noise. The sensors are connected to a fusion center through block-fading orthogonal multiple access channels. We introduce a new method, where: 1) for classification, an information-theoretic similarity measure known as correntropy is exploited by each local sensor; 2) for transmitting local decisions, an estimation of a priori probabilities is used by local sensors; and 3) for optimizing power allocation to each sensor, the Bhattacharyya distance is employed as the objective function by the fusion center. The proposed scheme improves the classification accuracy through exploiting channel diversity, which, in turn, enhances the overall performance. Simulation results validate the theoretically claimed improvement in the performance. © 2001-2012 IEEE.

Optimizing community-level surveillance data for pediatric asthma management

Item Type Journal Article

Author W.O. Benka-Coker

Author S.L. Gale

Author S.J. Brandt

Author J.R. Balmes

Author S. Magzamen

Abstract Community-level approaches for pediatric asthma management rely on locally collected information derived primarily from two sources: claims records and school-based surveys. We combined claims and school-based surveillance data, and examined the asthma-related risk patterns among adolescent students. Symptom data collected from school-based asthma surveys conducted in Oakland, CA were used for case identification and determination of severity levels for students (high and low). Survey data were matched to Medicaid claims data for all asthma-related health care encounters for the year prior to the survey. We then employed recursive partitioning to develop classification trees that identified patterns of demographics and healthcare utilization associated with severity. A total of 561 students had complete matched data; 86.1% were classified as high-severity, and 13.9% as low-severity asthma. The classification tree consisted of eight subsets: three indicating high severity and five indicating low severity. The risk subsets highlighted varying combinations of non-specific demographic and socioeconomic predictors of asthma prevalence, morbidity and severity. For example, the subset with the highest class-prior probability (92.1%) predicted high-severity asthma and consisted of students without prescribed rescue medication, but with at least one in-clinic nebulizer treatment. The predictive accuracy of the tree-based model was approximately 66.7%, with an estimated 91.1% of high-severity cases and 42.3% of low-severity cases correctly predicted. Our analysis draws on the strengths of two complementary datasets to provide community-level information on children with asthma, and demonstrates the utility of recursive partitioning methods to explore a combination of features that convey asthma severity. © 2018 The Authors

Optimizing text quantifiers for multivariate loss functions

Item Type Journal Article**Author** A. Esuli**Author** F. Sebastiani

Abstract We address the problem of quantification, a supervised learning task whose goal is, given a class, to estimate the relative frequency (or prevalence) of the class in a dataset of unlabeled items. Quantification has several applications in data and text mining, such as estimating the prevalence of positive reviews in a set of reviews of a given product or estimating the prevalence of a given support issue in a dataset of transcripts of phone calls to tech support. So far, quantification has been addressed by learning a general-purpose classifier, counting the unlabeled items that have been assigned the class, and tuning the obtained counts according to some heuristics. In this article, we depart from the tradition of using general-purpose classifiers and use instead a supervised learning model for structured prediction, capable of generating

classifiers directly optimized for the (multivariate and nonlinear) function used for evaluating quantification accuracy. The experiments that we have run on 5,500 binary high-dimensional datasets (averaging more than 14,000 documents each) show that this method is more accurate, more stable, and more efficient than existing state-of-the-art quantification methods. © 2015 ACM.

Abstract Quantification, i.e., the task of training predictors of the class prevalence values in sets of unlabelled data items, has received increased attention in recent years. However, most quantification research has concentrated on developing algorithms for binary and multiclass problems in which the classes are not ordered. We here study the ordinal case, i.e., the case in which a total order is defined on the set of $n > 2$ classes. We give three main contributions to this field. First, we create and make available two datasets for ordinal quantification (OQ) research that overcome the inadequacies of the previously available ones. Second, we experimentally compare the most important OQ algorithms proposed in the literature so far. To this end, we bring together algorithms that are proposed by authors from very different research fields, who were unaware of each other's developments. Third, we propose three OQ algorithms, based on the idea of preventing ordinally implausible estimates through regularization. Our experiments show that these algorithms outperform the existing ones if the ordinal plausibility assumption holds. © 2023, The Author(s), under exclusive license to Springer Nature Switzerland AG.

Outcome of HLA-oriented therapy for gastric cancer in retrospective and prospective study

Item Type Journal Article

Author K. Ogoshi

Author Y. Koyanagi

Author K. Tsuji

Author K. Isono

Abstract There are no strategies to predict a patient's response to therapy. In a previous report, we classified Japanese patients into four groups according to the incidence of HLA antigens, by using the quantification method III. We examined the HLA antigens of patients before surgery and evaluated their outcome according to the HLA classification by this quantification method. We also reported that HLA-oriented therapy was better than old fashioned therapy. The aim of the present study was to evaluate whether HLA classification is useful in the treatment of individual cancer patients, by using a consecutive retrospective study series of 1932 patients from Jan 1977 to May 1996 and a consecutive prospective study series of 582 patients from Jun 1996 to Aug 2005, all of whom received gastrectomies. There were significant differences between male patients who agreed to get the recommended therapy (the patients in agreement) and those who did not (the patients in disagreement), those with lymph node metastasis, those with undifferentiated adenocarcinoma, and those in stage 3A. Moreover, stage 2 and 3A patients benefitted from HLA-oriented therapy in a prospective study. In conclusion, our results showed that it is beneficial to examine HLA antigens preoperatively, that HLA-oriented therapy is promising, and that we must determine predictive factors for response to therapy in the future. We concluded that HLA antigens are promising predictive markers for cancer treatment.

Pain, sleep disturbances, and functional limitations in people living with hiv/ aids-associated distal sensory peripheral neuropathy

Item Type Journal Article

Author R. Sandoval

Author T. Roddey

Author T.P. Giordano

Author K. Mitchell

Author C. Kelley

Abstract Background: Pain, sleep, and functional disturbances are a common occurrence in people living with HIV/AIDS-related distal sensory peripheral neuropathy (PLWHA-DSPN) yet lack group classification and quantification. Methods: A total of 46 PLWHA-DSPN were recruited, as part of a 2-group intervention study, to complete the Neuropathic Pain Scale and the Pittsburgh Sleep Quality Index (PSQI) questionnaires. The participant's performance during a forward reach task and walking distance in 6 minutes was recorded as a measure of function. Results: The pain (60.77 ± 17.85) and sleep (14.62 ± 4.28) scores denote marked pain and sleep disturbances, compared to seronegative, age-matched individuals. The ambulation distance was limited (243.99 ± 141.04 m) and inversely associated with the PSQI-sleep efficiency subscale ($r_s = .35$, $P > .05$). The average reaching distances measured (36.07 ± 7.37 cm) were similar to seronegative, age-matched individuals. Pain, sleep, and functional measures exhibited significant associations. Conclusions: The data collected suggest that PLWHA-DSPN report moderate-to-severe pain and significant sleep disturbances and exhibit limited ambulation distances. © The Author(s) 2014.

Abstract Graph-based methods, pivotal for label inference over interconnected objects in many real-world applications, often encounter generalization challenges, if the graph used for model training differs significantly from the graph used for testing. This work delves into Graph Domain Adaptation (GDA) to address the unique complexities of distribution shifts over graph data, where interconnected data points experience shifts in features, labels, and in particular, connecting patterns. We propose a novel, theoretically principled method, Pairwise Alignment (Pair-Align) to counter graph structure shift by mitigating conditional structure shift (CSS) and label shift (LS). Pair-Align uses edge weights to recalibrate the influence among neighboring nodes to handle CSS and adjusts the classification loss with label weights to handle LS. Our method demonstrates superior performance in real-world applications, including node classification with region shift in social networks, and the pileup mitigation task in particle colliding experiments. For the first application, we also curate the largest dataset by far for GDA studies. Our method shows strong performance in synthetic and other existing benchmark datasets. Abstract We use deep transfer learning to quantify histopathological patterns across 17,355 hematoxylin and eosin-stained histopathology slide images from 28 cancer types and correlate these with matched genomic, transcriptomic and survival data. This approach accurately classifies cancer types and provides spatially resolved tumor and normal tissue distinction. Automatically learned computational histopathological features correlate with a large range of recurrent genetic aberrations across cancer types. This includes whole-genome duplications, which display universal features across cancer types, individual chromosomal aneuploidies, focal amplifications and deletions, as well as driver gene mutations. There are widespread associations between bulk gene expression levels and histopathology, which reflect tumor composition and enable the localization of transcriptomically defined tumor-infiltrating lymphocytes. Computational histopathology augments prognosis based on histopathological subtyping and grading, and highlights prognostically relevant areas such as necrosis or lymphocytic aggregates. These findings show the remarkable potential of computer vision in characterizing the molecular basis of tumor histopathology. © 2020, The Author(s), under exclusive licence to Springer Nature America, Inc.

Parathyroid gland identification and angiography classification using simple machine learning methods

Item Type Journal Article
Author P.D. Mcentee
Author J.E. Greevy
Author F. Triponez
Author M.S. Demarchi
Author R.A. Cahill

Abstract Background: Near-infrared indocyanine green angiography allows experienced surgeons to reliably evaluate parathyroid gland vitality during thyroid and parathyroid operations in order to predict postoperative function. To facilitate equal performance between surgeons, we developed an automatic computational quantification method using computer vision that portrays expert interpretation of visualized parathyroid gland near-infrared indocyanine green angiographic fluorescence signals. Methods: Near-infrared indocyanine green-parathyroid gland angiography video recordings (Fluobeam® LX, Fluoptics, Grenoble - part of Getinge - Göteborg) from patients undergoing endocrine cervical surgery in a high-volume unit were used for model development. Computation (MATLAB, Mathworks, Ireland) included segmentation-identification of the parathyroid gland (by autofluorescence), image stabilization (by linear translation) and adjusted time-fluorescence intensity profile generation. Relative upslope and maximum intensity ratios then trained a simple logistic regression model based on expert interpretation and outcome (including hypoparathyroidism), with subsequent unseen testing for validation. Results: The model was trained on 37 patient videos (45 glands, 29 judged well perfused by parathyroid gland angiography experts), achieving feature data separation with 100% accuracy, and tested on 22 unseen videos (27 glands, 15 judged well perfused), including four in real time. Segmentation-guided parathyroid gland detection correctly identified all parathyroid glands during unseen testing along with three additional non-parathyroid gland regions (90% positive predictive value). Subsequent time-fluorescence intensity profile extraction with vitality prediction was shown feasible in all cases within 5 min, with a 96.3% model accuracy (sensitivity and specificity were 93.3 and 100% respectively) when compared with expert judgement. Conclusion: Automatic parathyroid gland perfusion quantification using simple machine learning computational methods discriminates parathyroid gland perfusion in concordance with expert surgeon interpretation, providing a means for near-infrared indocyanine green-parathyroid gland signal evaluation. © 2024 The Author(s).

Partial AUC maximization in a linear combination of dichotomizers

Item Type Journal Article

Author M.T. Ricamato

Author F. Tortorella

Abstract Classifier combination is a useful and common methodology to design an effective classification system. A large number of combination rules has been proposed hitherto, mostly aimed at minimizing the error rate. Recently, some methods have been presented that are devoted to maximize the area under the ROC curve (AUC), a more suitable performance measure when dealing with two-class problems with imprecise environment and/or imbalanced class priors. However, there are several applications that do not operate in the complete range of the ROC curve, but only in particular regions of it. In these cases, it is better to analyze the performance only in a part of the curve and to use the partial AUC (pAUC). This paper presents a new method that aims at maximizing the pAUC by means of linear combination of classifiers. The effectiveness of the proposed method has been proved on two biometric databases. © 2011 Elsevier Ltd. All rights reserved.

Partial Domain Adaptation via Importance Sampling-Based Shift Correction

Item Type Journal Article**Author** C.-J. Guo**Author** C.-X. Ren**Author** Y.-W. Luo**Author** X.-L. Xu**Author** H. Yan

Abstract Partial domain adaptation (PDA) is a challenging task in real-world machine learning scenarios. It aims to transfer knowledge from a labeled source domain to a related unlabeled target domain, where the support set of the source label distribution subsumes the target one. Previous PDA works managed to correct the label distribution shift by weighting samples in the source domain. However, the simple reweighing technique cannot explore the latent structure and sufficiently use the labeled data, and then models are prone to over-fitting on the source domain. In this work, we propose a novel importance sampling-based shift correction (IS2C) method, where new labeled data are sampled from a built sampling domain, whose label distribution is supposed to be the same as the target domain, to characterize the latent structure and enhance the generalization ability of the model. We provide theoretical guarantees for IS2C by proving that the generalization error can be sufficiently dominated by IS2C. In particular, by implementing sampling with the mixture distribution, the extent of shift between source and sampling domains can be connected to generalization error, which provides an interpretable way to build IS2C. To improve knowledge transfer, an optimal transport-based independence criterion is proposed for conditional distribution alignment, where the computation of the criterion can be adjusted to reduce the complexity from $O(n^3)$ to $O(n^2)$ in realistic PDA scenarios. Extensive experiments on PDA benchmarks validate the theoretical results and demonstrate the effectiveness of our IS2C over existing methods. © 1992-2012 IEEE.

Passenger Comfort Quantification for Automated Vehicle Based on Stacking of Psychophysics Mechanism and Encoder-Transformer Model

Item Type Journal Article

Author W. Zhu

Author Z. Xi

Author C. Hu

Author B. Zhao

Author Y. Niu

Abstract Passenger comfort is a crucial aspect that influences humans' acceptance of automated vehicles. The passenger comfort score (PCS) is closely related to the passengers' psychological states, however, comfort quantification methods based on the passengers' psychophysics mechanism are rare. This research pioneers a

passenger comfort quantification model (PCQM) specifically designed for automated vehicles, demonstrating the model's ability to accurately quantify subjective PCS under urban LCS. Three significant contributions form the basis of this study: 1) A dataset dedicated to comfort quantification is collected. A novel PCQM based on ensemble learning of psychophysics mechanism based sub-model and encoder-transformer based sub-model is proposed. The psychophysics mechanism model is derived from Stevens' power law. 2) As a subjective indicator, the self-reported score (SRS), which is the indicator of PCS contains considerable noise. The PCQM addresses the issue of substantial noise prevalent in the subjective SRS by incorporating a semi-supervised learning strategy, which enhances data consistency and suppresses noise. 3) The efficacy of the proposed PCQM is corroborated via deployment on an automated vehicle, where the model's real-time predictions strongly align with SRS from onboard passengers. © 2000-2011 IEEE.

Patterns of Trauma Exposure in Childhood and Adolescence and Their Associations With Behavioral Well-Being

Item Type Journal Article

Author C.M. Connell

Author S.L. Pittenger

Author J.M. Lang

Abstract The majority of youth living in the United States experience a potentially traumatic event (PTE) by 18 years of age, with many experiencing multiple PTEs. Variation in the nature and range of PTE exposure differentially impacts youth functioning, although this association is poorly understood. We used latent class analysis (LCA) to identify patterns of PTE exposure from caregiver and youth report in a treatment-seeking sample of children and adolescents (N = 701) and examined how these patterns predict youths' behavioral health outcomes. We identified four classes based on both caregiver and youth reports of PTE exposure, with the best-fitting model representing a constrained measurement model across reporters; these included high polyvictimization, moderate polyvictimization (general), moderate polyvictimization (interpersonal), and low polyvictimization classes. Prevalence of classes varied across reporters, and agreement in classification based on caregiver and youth report was mixed. Despite these differences, we observed similar patterns of association between caregiver- and youth-reported classes and their respective ratings of posttraumatic stress disorder and depressive symptoms, as well as both caregiver and therapist ratings of problem behavior, with Cohen's d effect size estimates of significant differences ranging from d = 0.25 to d = 0.51. The PTE exposure classes did not differ with respect to ratings of child functioning. Findings highlight the importance of gathering information from multiple informants. © 2018 International Society for Traumatic Stress Studies

Paying attention to cardiac surgical risk: An interpretable machine learning approach using an uncertainty-aware attentive neural network

Item Type Journal Article

Author J.C. Penny-Dimri

Author J. Williams-Spence

Author A.D. Cochrane

Author J.A. Smith

Abstract Machine learning (ML) is increasingly applied to predict adverse postoperative outcomes in cardiac surgery. Commonly used ML models fail to translate to clinical practice due to absent model explainability, limited uncertainty quantification, and no flexibility to missing data. We aimed to develop and benchmark a novel ML approach, the uncertainty-aware attention network (UAN), to overcome these common limitations. Two Bayesian uncertainty quantification methods were tested, generalized variational inference (GVI) or a posterior network (PN). The UAN models were compared with an ensemble of XGBoost models and a Bayesian logistic regression model (LR) with imputation. The derivation datasets consisted of 153,932 surgery events from the Australian and New Zealand Society of Cardiac and Thoracic Surgeons (ANZSCTS) Cardiac Surgery Database. An external validation consisted of 7343 surgery events which were extracted from the Medical Information Mart for Intensive Care (MIMIC) III critical care dataset. The highest performing model on the external validation dataset was a UAN-GVI with an area under the receiver operating characteristic curve (AUC) of 0.78 (0.01). Model performance improved on high confidence samples with an AUC of 0.81 (0.01). Confidence calibration for aleatoric uncertainty was excellent for all models. Calibration for epistemic uncertainty was more variable, with an ensemble of XGBoost models performing the best with an AUC of 0.84 (0.08). Epistemic uncertainty was improved using the PN

approach, compared to GVI. UAN is able to use an interpretable and flexible deep learning approach to provide estimates of model uncertainty alongside state-of-the-art predictions. The model has been made freely available as an easy-to-use web application demonstrating that by designing uncertainty-aware models with innately explainable predictions deep learning may become more suitable for routine clinical use. © 2023 Penny-Dimri et al.

Pear flower cluster quantification using RGB drone imagery

Item Type Journal Article

Author Y. Vanbrabant

Author S. Delalieux

Author L. Tits

Author K. Pauly

Author J. Vandermaesen

Author B. Somers

Abstract High quality fruit production requires the regulation of the crop load on fruit trees by reducing the number of flowers and fruitlets early in the growing season, if the bearing is too high. Several automated flower cluster quantification methods based on proximal and remote imagery methods have been proposed to estimate flower cluster numbers, but their overall performance is still far from satisfactory. For other methods, the performance of the method to estimate flower clusters within a tree is unknown since they were only tested on images from one perspective. One of the main reported bottlenecks is the presence of occluded flowers due to limitations of the top-view perspective of the platform-sensor combinations. In order to tackle this problem, the multi-view perspective from the Red–Green–Blue (RGB) colored dense point clouds retrieved from drone imagery are compared and evaluated against the field-based flower cluster number per tree. Experimental results obtained on a dataset of two pear tree orchards (N = 144) demonstrate that our 3D object-based method, a combination of pixel-based classification with the stochastic gradient boosting algorithm and density-based clustering (DBSCAN), significantly outperforms the state-of-the-art in flower cluster estimations from the 2D top-view ($R^2 = 0.53$), with $R^2 > 0.7$ and $RRMSE < 15\%$. © 2020 by the authors.

Author J.G. Ibrahim

Author Y. Fan

Abstract There is an emerging interest in brain functional connectivity (FC) based on functional Magnetic Resonance Imaging in Alzheimer's disease (AD) studies. The complex and high-dimensional structure of FC makes it challenging to explore the association between altered connectivity and AD susceptibility. We develop a pipeline to refine FC as proper covariates in a penalized logistic regression model and classify normal and AD susceptible groups. Three different quantification methods are proposed for FC refinement. One of the methods is dimension reduction based on common component analysis (CCA), which is employed to address the limitations of the other methods. We applied the proposed pipeline to the Alzheimer's Disease Neuroimaging Initiative (ADNI) data and deduced pathogenic FC biomarkers associated with AD susceptibility. The refined FC biomarkers were related to brain regions for cognition, stimuli processing, and sensorimotor skills. We also demonstrated that a model using CCA performed better than others in terms of classification performance and goodness-of-fit. © 2020 The Korean Statistical Society, and Korean International Statistical Society. Author	S.H. Supangkat
Abstract	This study introduces a vehicle volume analysis system utilizing video analytics technology to improve traffic counting accuracy at intersections using CRISP-DM methodology. By leveraging the YOLO (You Only Look Once) algorithm, it can detect, classify, and count vehicles using footage from public CCTV cameras based on Indonesian Road Capacity Manual. This research focuses on a four-way intersection in Sedayu, Yogyakarta, Indonesia, and involves preparing a dataset by extracting and labeling video frames. This research train and evaluate several YOLO models-YOLOv5s, YOLOv7, YOLOv8s, and Gelan-c from YOLOv9-to assess their effectiveness in real-world traffic scenarios. The results demonstrate that YOLOv8s delivers superior performance compared to the other versions, achieving a precision of 0.971 and a recall of 0.988 across all vehicle classes. This high accuracy highlights the potential of YOLOv8s for improving traffic volume counting at busy intersections. However, challenges remain, including false positives, double detections, and misclassifications, which tend to occur under certain traffic conditions, such as low visibility or dense vehicle clustering. Despite these issues, YOLOv8s shows promise for enhancing the efficiency and precision of traffic analysis systems. The contribution of this paper is to support the evaluation of intersection performance based on turn movement count in accordance with the Indonesian Road Capacity Manual, where currently the evaluation is still carried out manually. Future research will focus on addressing these challenges by refining the detection process and incorporating additional techniques, such as advanced post-processing methods and model enhancements, to increase robustness in various traffic environments. © 2024 IEEE.

Performance evaluation of fuzzy rule-based systems with class priority for medical diagnosis problems

Item Type Conference Paper
Author T. Nakashima
Author Y. Yokota
Author G. Schaefer
Author H. Ishibuchi
Abstract In this paper we examine the performance of fuzzy rule-based systems with classification priority for medical diagnosis problems. The assumption in this paper is that a classification priority is given a priori for each class in a pattern classification problem. Our fuzzy rule-based system consists of a set of fuzzy if-then rules that are automatically generated from a set of given training patterns. The consequent class of fuzzy if-then rules are decided based on the number of covered training patterns for each class. We apply the fuzzy classifier with class priority to two medical diagnosis problems: appendix diagnosis and breast cancer diagnosis, and compare its performance with that of a conventional fuzzy rule-based systems. © 2007 ECMS.

Performance metrics for marine mammal signal detection and classification

Item Type Journal Article

Author J.A. Hildebrand

Author K.E. Frasier

Author T.A. Helble

Author M.A. Roch

Abstract Automatic algorithms for the detection and classification of sound are essential to the analysis of acoustic datasets with long duration. Metrics are needed to assess the performance characteristics of these algorithms. Four metrics for performance evaluation are discussed here: receiver-operating-characteristic (ROC) curves, detection-error-trade-off (DET) curves, precision-recall (PR) curves, and cost curves. These metrics were applied to the generalized power law detector for blue whale D calls [Helble, Ierley, D'Spain, Roch, and Hildebrand (2012). J. Acoust. Soc. Am. 131(4), 2682-2699] and the click-clustering neural-net algorithm for Cuvier's beaked whale echolocation click detection [Frasier, Roch, Soldevilla, Wiggins, Garrison, and Hildebrand (2017). PLoS Comp. Biol. 13(12), e1005823] using data prepared for the 2015 Detection, Classification, Localization and Density Estimation Workshop. Detection class imbalance, particularly the situation of rare occurrence, is common

for long-term passive acoustic monitoring datasets and is a factor in the performance of ROC and DET curves with regard to the impact of false positive detections. PR curves overcome this shortcoming when calculated for individual detections and do not rely on the reporting of true negatives. Cost curves provide additional insight on the effective operating range for the detector based on the a priori probability of occurrence. Use of more than a single metric is helpful in understanding the performance of a detection algorithm. © 2022 Author(s).

Abstract Intra-operative (this work was partially supported by Disruptive Technologies Innovation Fund, Ireland, project code DTIF2018 240 CA) identification of malignant versus benign or healthy tissue is a major challenge in fluorescence guided cancer surgery. We propose a perfusion quantification method for computer-aided interpretation of subtle differences in dynamic perfusion patterns which can be used to distinguish between normal tissue and benign or malignant tumors intra-operatively by using multispectral endoscopic videos. The method exploits the fact that vasculature arising from cancer angiogenesis gives tumors differing perfusion patterns from the surrounding normal tissues. Experimental evaluation of our method on a cohort of colorectal cancer surgery endoscopic videos suggests that it discriminates between healthy, cancerous and benign tissues with 95% accuracy. © 2020, Springer Nature Switzerland AG.

Persistent Homology for the Quantitative Evaluation of Architectural Features in Prostate Cancer Histology

Item Type Journal Article

Author P. Lawson

Author A.B. Sholl

Author J.Q. Brown

Author B.T. Fasy

Author C. Wenk

Abstract The current system for evaluating prostate cancer architecture is the Gleason grading system which divides the morphology of cancer into five distinct architectural patterns, labeled 1 to 5 in increasing levels of cancer aggressiveness, and generates a score by summing the labels of the two most dominant patterns. The Gleason score is currently the most powerful prognostic predictor of patient outcomes; however, it suffers from problems in reproducibility and consistency due to the high intra-observer and inter-observer variability amongst pathologists. In addition, the Gleason system lacks the granularity to address potentially prognostic architectural features beyond Gleason patterns. We evaluate prostate cancer for architectural subtypes using techniques from topological data analysis applied to prostate cancer glandular architecture. In this work we demonstrate the use of persistent homology to capture architectural features independently of Gleason patterns. Specifically, using persistent homology, we compute topological representations of purely graded prostate cancer histopathology images of Gleason patterns 3,4 and 5, and show that persistent homology is capable of clustering prostate cancer histology into architectural groups through a ranked persistence vector. Our results indicate the ability of persistent homology to cluster prostate cancer histopathology images into unique groups with dominant architectural patterns consistent with the continuum of Gleason patterns. In addition, of particular interest, is the sensitivity of persistent homology to identify specific sub-architectural groups within single Gleason patterns, suggesting that persistent homology could represent a robust quantification method for prostate cancer architecture with higher granularity than the existing semi-quantitative measures. The capability of these topological representations to segregate prostate cancer by architecture makes them an ideal

candidate for use as inputs to future machine learning approaches with the intent of augmenting traditional approaches with topological features for improved diagnosis and prognosis. © 2019, The Author(s).

Abstract Purpose: To evaluate whether whole-body PET/CT-derived body composition features are associated with survival in patients with resectable non-small cell lung cancer (NSCLC), using double machine learning to quantify adjusted associations with restricted mean survival time. Methods: This retrospective multicenter study included 769 patients with stage $\leq$ IIIA NSCLC who underwent preoperative 18F-fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET/CT) and curative resection. Center 1 was used for model development (n = 555) and Center 2 for external validation (n = 214). Automated whole-body segmentation was used to extract volumetric, attenuation-based and metabolic features of skeletal muscle and adipose tissue. Restricted mean survival time-based double machine learning with generalized propensity score weighting estimated DML-adjusted differences in restricted mean survival time for overall survival (OS) and progression-free survival (PFS). Ridge-penalized Cox models were further used to evaluate prognostic performance and incremental value. Results: Higher intermuscular adipose tissue (IMAT) volume index was associated with shorter survival (DML-adjusted RMST difference, -4.29 months for OS and - 2.74 months for PFS per 1-SD higher IMAT volume index). Higher TAT SUR (Mean) showed an exploratory favorable adjusted association with longer OS (+ 4.42 months). Sex-stratified analyses suggested stronger adverse adipose-volume associations in male patients and stronger favorable adipose-metabolic associations in female patients. Model analyses showed moderate external discrimination, whereas incremental-value metrics were modest and endpoint-dependent. Conclusion: Whole-body PET/CT body-composition phenotyping may provide prognostic information in resectable NSCLC. Higher IMAT burden was associated with shorter survival, whereas TAT SUR (Mean) showed an exploratory favorable adjusted association with OS. A local software framework may support reproducible feature extraction and research-oriented risk stratification. © The Author(s) 2026.

Photocatalytic nitrogen reduction to ammonia: Insights into the role of defect engineering in photocatalysts

Item Type Journal Article**Author** H. Shen**Author** M. Yang**Author** L. Hao**Author** J. Wang**Author** J. Strunk**Author** Z. Sun

Abstract Engineering of defects in semiconductors provides an effective protocol for improving photocatalytic N₂ conversion efficiency. This review focuses on the state-of-the-art progress in defect engineering of photocatalysts for the N₂ reduction toward ammonia. The basic principles and mechanisms of thermal catalyzed and photon-induced N₂ reduction are first concisely recapped, including relevant properties of the N₂ molecule, reaction pathways, and NH₃ quantification methods. Subsequently, defect classification, synthesis strategies, and identification techniques are compendiously summarized. Advances of in situ characterization techniques for monitoring defect state during the N₂ reduction process are also described. Especially, various surface defect strategies and their critical roles in improving the N₂ photoreduction performance are highlighted, including surface vacancies (i.e., anionic vacancies and cationic vacancies), heteroatom doping (i.e., metal element doping and nonmetal element doping), and atomically defined surface sites. Finally, future opportunities and challenges as well as perspectives on further development of defect-engineered photocatalysts for the nitrogen reduction to ammonia are presented. It is expected that this review can provide a profound guidance for more specialized design of defect-engineered catalysts with high activity and stability for nitrogen photochemical fixation. Physical and Physiological Responses during Competition

Item Type Journal Article

Author J. Yanci

Author A. Iturricastillo

Author M. Henríquez

Author D. Castillo

Abstract The aim of this chapter is to analyse the physical and physiological responses of football players with CP in competitive matches. To achieve this, a narrative review was conducted, including the principal studies that explore the physical and physiological responses of this specific group of para-footballers. In the introduction section, the importance of analysing the match physical and physiological responses of players with CP and their implications for training, classification and competition is described. In the physical and physiological responses sections, the most relevant material and quantification methods are presented, considering the available data compiled and examined from recent literature. It is known that contextual variables can influence the match physical responses of players; therefore, these different

contextual variables are taken into account. To conclude the chapter, the practical applications section is presented, along with future research needs in the field. © 2025 selection and editorial matter, Iván Peña-González, Raúl Reina and Manuel Moya-Ramón; individual chapters, the contributors.

Physics-informed neural networks for capturing the true relationships between parameters to predict the dynamic triaxial strength of rocks in cold environments

Item Type Journal Article

Abstract Due to freeze–thaw cycles, rocks in cold regions are prone to fatigue damage, making the accurate prediction of their dynamic triaxial strength critical for mining engineering in cold regions. A physics-informed neural network (PINN) approach was proposed, integrating rock mechanics theory with neural networks to improve prediction accuracy, interpretability, and generalization. To enhance reliability, an uncertainty-aware PINN (UAPINN) model was developed by incorporating uncertainty quantification. To assess UAPINN model performance, six machine learning models were developed, and their performance was evaluated using metrics such as R2, MAE, RMSE and VAF. A feature importance quantification method

based on Bayesian neural network uncertainty analysis was introduced. The results show that the UAPINN model outperforms traditional models, with the performance ranking: UAPINN > PINN > LightGBM > CatBoost > GRU > ELM > RF > SVR. Feature importance analysis reveals that the most influential parameters for dynamic triaxial strength are confining pressure > P-wave velocity > strain rate > freeze–thaw cycles > water absorption > dry density. This study provides an efficient method for predicting rock strength in cold-region engineering applications. © 2025 Elsevier Ltd

Abstract Self-supervised learning is a powerful approach for developing traversability models for off-road navigation, but these models often struggle with inputs unseen during training. Existing methods utilize techniques like evidential deep learning to quantify model uncertainty, helping to identify and avoid out-of-distribution terrain. However, always avoiding out-of-distribution terrain can be overly conservative, e.g., when novel terrain can be effectively analyzed using a physics-based model. To overcome this challenge, we introduce Physics-Informed Evidential Traversability (PIETRA), a self-supervised learning framework that integrates physics priors directly into the mathematical formulation of evidential neural networks and introduces physics knowledge implicitly through an uncertainty-aware, physics-informed training loss. Our evidential network seamlessly transitions between learned and physics-based predictions for out-of-distribution inputs. Additionally, the physics-informed loss regularizes the learned model, ensuring better alignment with the physics model. Extensive simulations and hardware experiments demonstrate that PIETRA improves both learning accuracy and navigation performance in environments with significant distribution shifts. © 2016 IEEE.

Pipeline defect size quantification via multi-branch online distillation with magnetic flux leakage priors and adaptive fusion

Item Type Journal Article

Author J. Li

Author H. Geng

Author W. Shao

Author B. Liu

Author L. Yang

Abstract Due to the complex industrial inspection environment, the limited number of labeled defect samples, and the insufficient exploitation of inherent defect characteristics in existing quantification methods, achieving accurate and reliable high-precision three-dimensional size quantification of defects directly from magnetic flux leakage signals remains challenging. To address the above issues, this paper proposes a pipeline magnetic flux leakage (MFL) defect three-dimensional sizing method based on multi-branch online knowledge distillation. This method takes the collected three-axis MFL data as input, extracts information in a targeted manner via multiple branches, and leverages the Magnetic-prior Network (Net-M) branch to effectively fuse prior knowledge and features. The adaptive fusion subnet (AFS) is introduced to adaptively fuse extracted data features, thereby enhancing the model's robustness and interpretability in few-shot scenarios and under practical signal disturbances. In addition, a dual supervised learning mechanism is incorporated to ensure stable model training, and finally, collaborative regression outputs of defect length, width, and depth are obtained. Extensive experiments conducted on the MFL defect data from the pull-through tests of the $\Phi 1016$ pipeline show that the average quantification errors of the proposed method are 0.67 mm in length, 1.51 mm in width, and 0.60 mm in depth. The proposed method improves the defect sizing accuracy by >10%, and its detection precision meets the requirements of ultra-high-definition pipeline inline inspection (ILI) equipment. It enables intelligent batch-level quantification of pipeline defect dimensions and maintains high performance with a total dataset size of 50 and across different pipe diameters. © 2026 The Authors.

Pitfalls in Quantification Assessment

Item Type Conference Paper**Author** W. Hassan**Author** A. Maletzke**Author** G. Batista**Editor** Cong G.**Editor** Ramanath M.

Abstract Quantification is a research area that develops methods that estimate the class attribute prevalence in an independent sample. Like the other fields in Machine Learning, quantification researchers often use experimental assessment to evaluate and compare the performance of their proposals. Therefore, the design of the experimental protocols is critical to the research in quantification. Currently, two protocols have dominated the assessment of quantifiers: the artificial-prevalence protocol (APP) and the natural-prevalence protocol (NPP). APP is the most employed since it allows the use of classification datasets, plenty available. However, APP has a shortcoming: the synthetic class prevalence of the test sets. This paper discusses the practical consequences of this shortcoming and shows simple examples of quantifiers that exploit these limitations to improve their performance artificially. We propose a baseline quantifier, lazy, and radar charts as tools to identify situations where the proposed quantifiers are performing poorly. © 2021 Copyright for this paper by its authors. Plant recognition by AI: Deep neural nets, transformers, and kNN in deep embeddings

Item Type Journal Article

Author L. Picek

Author M. Šulc

Author Y. Patel

Author J. Matas

Abstract The article reviews and benchmarks machine learning methods for automatic image-based plant species recognition and proposes a novel retrieval-based method for recognition by nearest neighbor classification in a deep embedding space. The image retrieval method relies on a model trained via the Recall@k surrogate loss. State-of-the-art approaches to image classification, based on Convolutional Neural Networks (CNN) and Vision Transformers (ViT), are benchmarked and compared with the proposed image retrieval-based method. The impact of performance-enhancing techniques, e.g., class prior adaptation, image augmentations, learning rate scheduling, and loss functions, is studied. The evaluation is carried out on the PlantCLEF 2017, the ExpertLifeCLEF 2018, and the iNaturalist 2018 Datasets—the largest publicly available datasets for plant recognition. The evaluation of CNN and ViT classifiers shows a gradual improvement in classification accuracy. The current state-of-the-art Vision Transformer model, ViT-Large/16, achieves 91.15% and 83.54% accuracy on the PlantCLEF 2017 and ExpertLifeCLEF 2018 test sets,

respectively; the best CNN model (ResNeSt-269e) error rate dropped by 22.91% and 28.34%. Apart from that, additional tricks increased the performance for the ViT-Base/32 by 3.72% on ExpertLifeCLEF 2018 and by 4.67% on PlantCLEF 2017. The retrieval approach achieved superior performance in all measured scenarios with accuracy margins of 0.28%, 4.13%, and 10.25% on ExpertLifeCLEF 2018, PlantCLEF 2017, and iNat2018–Plantae, respectively. Abstract The paper describes an automatic system for recognition of 10, 000 plant species from one or more images. The system finished 1st in the ExpertLifeCLEF 2018 plant identification challenge with 88.4% accuracy and performed better than 5 of the 9 participating plant identification experts. The system is based on the Inception-ResNet-v2 and Inception-v4 Convolutional Neural Network (CNN) architectures. Performance improvements were achieved by: adjusting the CNN predictions according to the estimated change of the class prior probabilities, replacing network parameters with their running averages, and test-time data augmentation.

PlasmaCell CAD: A computer-aided diagnosis software tool for plasma cell recognition and characterization in microscopic images

Item Type Journal Article

Author R. Kasbgar

Author A. Vard

Abstract Background and objective: In the traditional diagnostic process for multiple myeloma cancer, a pathologist screens prepared blood samples using a microscope to detect, classify, and count plasma cells. This manual approach is time-consuming, exhausting, and prone to human errors. Consequently, medical experts and researchers are highly interested in any tool that partially or entirely automates this process. To achieve this goal, we developed a software tool called PlasmaCell CAD to analyze effective cells for diagnosing multiple myeloma cancers through microscopic images. Methods: In the proposed software, to detect and segment cells, we exploit the Mask-RCNN model that has been enhanced by leveraging the circlet transform for the anchor generation. Also, we use the SVM classifier to identify normal and abnormal plasma cells in this software. Moreover, we designed and developed a graphical user interface (GUI) for the PlasmaCell CAD so that users would be able to work with it more easily. Results: we considered the performance of the proposed software on both a publicly available dataset and a locally collected dataset. The experimental results demonstrated the capability and efficiency of PlasmaCell CAD software in segmenting and classifying plasma cells as well as its ease of use. Conclusions: PlasmaCell CAD is a free software tool that can easily be downloaded and installed on any computers running Windows. PlasmaCell CAD provides a user-friendly GUI with several image processing and visualization facilities for the user that can accelerate the diagnosis process. In light of promising results, PlasmaCell CAD software can be useful to pathologists in helping to diagnose multiple myeloma cancer. © 2025 Elsevier B.V.

POETIC-NET: an augmented contextual feature representation via graph centrality relation for emotion recognition of English poetry

Item Type Journal Article

Author P.K. Kazipeta

Author V.P.K. Sistla

Author V.K.K. Kolli

Abstract The task of extracting emotion from poetry data is one that has received little attention in the literature. Poetry has a complex structure and emotional richness, in contrast to prose data such as tweets, product reviews, emails, and chats. This disparity makes the prediction of emotions from the poetry a challenging endeavor. Many prior studies focus on capturing emotions derived from local relations while overlooking a poem's global relations. This study introduces Poetic-Net, a multi-channel neural architecture for effective emotion recognition in poetry that leverages both structural and contextual insights. The model integrates Global Centrality Relation (GCR) features extracted via graph-based learning to quantify each word's contribution to a poem's central theme, and contextual features derived by passing BERT-pretrained embeddings through a sequence of Bi-LSTM, CNN, and Attention layers. By fusing GCR and deep contextual representations, Poetic-Net becomes a robust system that captures subtle and complex emotional patterns inherent in poetic text. Poetic-Net classifies poetry into five emotion classes viz. "Happy," "Fear," "Sad," "Angry," and "Surprise". Due to the unavailability of public datasets on emotion-annotated English poetry, an English poetry dataset ABIEMO (American,

British, and Indian Poetry datasets for Emotion detection) is developed to evaluate the performance of the proposed model. The proposed Poetic-Net is evaluated with five-word representations (GloVe, FastText, Word2vec-CBOW, Word2vec-SkipGram, and BERT) against baseline classification models. The proposed Poetic-Net model outperformed all the baseline models with an accuracy of 92.89% as both global and contextual features contributed significantly in feature extraction for improved performance. © The Author(s), under exclusive licence to Springer-Verlag GmbH Germany, part of Springer Nature 2026.

Poisoning-Assisted Membership Inference in Federated Learning

Item Type Journal Article

Author X. Luan

Author Y. Bi

Author K. Zhang

Author Z. Huang

Author Z. Su

Author T.H. Luan

Author B. Hu

Abstract Federated learning (FL) is a distributed machine learning approach that allows multiple clients to collaboratively train a global model without sharing their local raw data. Despite this advantage, FL remains vulnerable to membership inference attacks (MIAs), which can compromise the membership privacy of federated clients. Nevertheless, existing MIAs exhibit significant performance degradation when the malicious clients lack knowledge of the target model and the training data of benign clients. In this paper, we propose a novel scheme, Temporal Evolution of the Poisoning Effects (TEPE), to conduct MIAs against black-box FL models without any prior knowledge of the target models or benign clients' training data. Specifically, we design a two-stage inference method: the poisoning process and the scoring process. For the poisoning process, we propose three poisoning strategies for three different auditing requirements. For the scoring process, we design a novel quantification method and an unsupervised inference model to extract membership features within the effects of poisoning attacks. The proposed attack leverages the intuition that if a sample is used by FL benign clients, its prediction may not be readily altered by poisoning attacks. Finally, we propose a modified random response algorithm (RR-Group) to detect our attacks, which can guarantee the performance of FL models and effectively reduce the attack performance of TEPE. Extensive experiments demonstrate that TEPE achieves competitive inference accuracy and F1-score compared to the most MIAs, while evading two representative defenses, except for our proposed detection method RR-Group. © 2004 IEEE.

Abstract Digital polymerase chain reaction (dPCR) is a state-of-the-art targeted quantification method of nucleic acids. The technology is based on massive partitioning of a reaction mixture into individual PCR reactions. The resulting partition-level end-point fluorescence intensities are used to classify partitions as positive or negative, i.e. containing or not containing the target nucleic acid(s). Many automatic dPCR partition classification methods have been proposed, but they are limited to the analysis of single- or dual-color dPCR data. While general-purpose or flow cytometry clustering methods can be directly applied to multicolor dPCR data, these methods do not exploit the approximate prior knowledge on cluster center locations available in dPCR data. We present Polytect, a method that relies on crude cluster results from flowPeaks, previously shown to offer good partition classification performance, and subsequently refines flowPeaks' results by automatic cluster merging and cluster labeling, exploiting the prior knowledge on cluster center locations. Comparative analyses with established methods such as flowPeaks, dpcp, and ddPCRclust reveal that Polytect often surpasses established methods, both on empirical and simulated data. Polytect manages to merge excess clusters, while also successfully identifying empty clusters when fewer than the maximally observable number of clusters are present. On par with recent developments in instruments, Polytect extends beyond two-color data. The method is available as an R package and R Shiny app (<https://digpcr.shinyapps.io/Polytect/>). © 2025 The Author(s).

Pornographic image classification based on top down color-saliency based BoW representation

Item Type Conference Paper

Author C. Tian

Author X. Zhang

Author X. Gao

Author W. Wei

Abstract Since color is an important visual clue of the pornographic image, this study presents a new framework for pornographic image classification based on the fusion of color and shape information for the bag of words representation. This framework contains three fusion patterns: The early fusion, late fusion and top down color-saliency based fusion, which are compared intensively. Based on the comparison, the top down color-saliency fusion based pornographic image classification method is proposed by using the statistical class prior of each color word to weight the shape word. In the late fusion and color-saliency based fusion, color name is adopt to represent the color information. To verify the effectiveness of spatial constrain on the words, we also compared the shape features quantized by vector quantization and locality-constrained linear coding. The experimental results show that our model combines the shape and color information properly and it is superior over the popular methods to distinguish the normal and pornographic-like images from the pornographic ones. © 2014 IEEE.

Abstract Federated Learning (FL) enables collaborative model training across distributed clients without requiring the exchange of raw data. However, existing One-Shot FL (OSFL) methods, designed for communication efficiency by reducing federated rounds to one, suffer substantial performance degradation when faced with highly non-IID data across clients, primarily due to critical distribution shifts: label shift, feature shift, and concept shift. In this paper, we introduce POSFed, a new personalized three-stage approach, to systematically address these fundamental limitations: (1) Each client locally generates robust and label-agnostic synthetic datasets via self-supervising learning, ensuring essential knowledge is captured despite local distribution shifts; (2) The server aggregates all synthetic datasets to train a global feature extractor, capturing generalizable and transferable representations across heterogeneous client data; and (3) Each client efficiently adapts the feature extractor by learning a personalized classification head on its own data, enabling effective local customization and mitigating both feature and concept shifts. Extensive experiments across multiple benchmarks demonstrate that POSFed significantly outperforms state-of-the-art methods, achieving performance comparable to multi-round personalized approaches while using only one communication round. By ensuring both superior personalization and practical communication efficiency, POSFed establishes a feasible paradigm for FL under more realistic and heterogeneous conditions. Posistive-Unlabeled Learning via Optimal Transport and Margin Distribution

Item Type Conference Paper

Author N. Cao

Author T. Zhang

Author X. Shi

Author H. Jin

Editor De Raedt L.

Editor De Raedt L.

Abstract Positive-unlabeled (PU) learning deals with the circumstances where only a portion of positive instances are labeled, while the rest and all negative instances are unlabeled, and due to this confusion, the class prior can not be directly available. Existing PU learning methods usually estimate the class prior by training a nontraditional probabilistic classifier, which is prone to give an overestimation. Moreover, these methods learn the decision boundary by optimizing the minimum margin, which is not suitable in PU learning due to its sensitivity to label noise. In this paper, we enhance PU learning methods from the above two aspects. More specifically, we first explicitly learn a transformation from unlabeled data to positive data by entropy regularized optimal transport to achieve a much more precise estimation for class prior. Then we switch to optimizing the margin distribution, rather than the minimum margin, to obtain a label noise insensitive classifier. Extensive empirical studies on both synthetic and real-world data sets demonstrate the superiority of our proposed method. © 2022 International Joint Conferences on Artificial Intelligence. Positive and unlabeled learning for anomaly detection with multi-features

Item Type Conference Paper

Author J. Zhang

Author Z. Wang

Author J. Yuan

Author Y.-P. Tan

Abstract Anomaly detection is of great interest to big data applications, and both supervised and unsupervised learning have been applied for anomaly detection. However, it still remains a challenging problem because: (1) for supervised learning, it is difficult to acquire training data for anomaly samples; while (2) for unsupervised learning, the performance may not be satisfactory due to the lack of training data. To address the limitations, we propose a hybrid solution by using both normal (positive) data and unlabeled data (could be positive or negative) for semi-supervised anomaly detection. Particularly, we introduce a new framework based on Positive and Unlabeled (PU) Learning using multi-features to detect anomalies. We extend previous PU learning methods to (1) better address unbalanced class problem which is typical for anomaly detection, and (2) handle multiple features for anomaly detection. An iterative algorithm is proposed to learn the anomaly classifier incrementally from the labeled normal data and also unlabeled data. Our proposed method is verified on three benchmark datasets and one synthetic dataset. Experimental results show that our method outperforms existing methods under different class priors and different proportions of given positive classes. © 2017 ACM.

Positive Unlabeled Learning Selected Not At Random (PULSNAR): class proportion estimation without the selected completely at random assumption

Item Type Journal Article

Author P. Kumar

Author C.G. Lambert

Abstract Positive and unlabeled (PU) learning is a type of semi-supervised binary classification where the machine learning algorithm differentiates between a set of positive instances (labeled) and a set of both positive and negative instances (unlabeled). PU learning has broad applications in settings where confirmed negatives are unavailable or difficult to obtain, and there is value in discovering positives among the unlabeled (e.g., viable drugs among untested compounds). Most PU learning algorithms make the selected completely at random (SCAR) assumption, namely that positives are selected independently of their features. However, in many real-world applications, such as healthcare, positives are not SCAR (e.g., severe cases are more likely to be diagnosed), leading to a poor estimate of the proportion, α , of positives among unlabeled examples and poor model calibration, resulting in an uncertain decision threshold for selecting positives. PU learning algorithms vary; some estimate only the proportion, α , of positives in the unlabeled set, while others calculate the probability that each specific unlabeled instance is positive, and some can do both. We propose two PU learning algorithms to estimate α , calculate

calibrated probabilities for PU instances, and improve classification metrics: i) PULSCAR (positive unlabeled learning selected completely at random), and ii) PULSNAR (positive unlabeled learning selected not at random). PULSNAR employs a divide-and-conquer approach to cluster SNAR positives into subtypes and estimates α for each subtype by applying PULSCAR to positives from each cluster and all unlabeled. In our experiments, PULSNAR outperformed state-of-the-art approaches on both synthetic and real-world benchmark datasets. © 2024 Kumar and Lambert

Positive unlabeled learning with class-prior approximation

Item Type Conference Paper

Author S. Chang

Author B. Du

Author L. Zhang

Editor Bessiere C.

Abstract The positive unlabeled (PU) learning aims to train a binary classifier from a set of positive labeled samples and other unlabeled samples. Much research has been done on this special branch of weakly supervised classification problems. Since only part of the positive class is labeled, the classical PU model trains the classifier assuming the class-prior is known. However, the true class prior is usually difficult to obtain and must be learned from the given data, and the traditional methods may not work. In this paper, we formulate a convex formulation to jointly solve the class-prior unknown problem and train an accurate classifier with no need of any class-prior assumptions or additional negative samples. The class prior is estimated by pursuing the optimal solution of gradient thresholding and the classifier is simultaneously trained by performing empirical unbiased risk. The detailed derivation and theoretical analysis of the proposed model are outlined, and a comparison of our experiments with other representative methods prove the superiority of our method. © 2020 Inst. Positive-unlabeled classification under class prior shift and asymmetric error

Item Type Conference Paper

Author N. Charoenphakdee

Author M. Sugiyama

Abstract Bottlenecks of binary classification from positive and unlabeled data (PU classification) are the requirements that given unlabeled patterns are drawn from the same distribution as the test distribution, and the penalty of the false positive error is identical to the false negative error. However, such requirements are often not fulfilled in practice. In this paper, we generalize PU classification to the class prior shift and asymmetric error scenarios. Based on the analysis of the Bayes optimal classifier, we show that given a test class prior, PU classification under class prior shift is equivalent to PU classification with asymmetric error. Then, we propose two different frameworks to handle these problems, namely, a risk minimization framework and density ratio estimation framework. Finally, we demonstrate the effectiveness of the proposed frameworks through experiments. Copyright © 2019 by SIAM.

Positive-unlabeled classification under class-prior shift: a prior-invariant approach based on density ratio estimation

Item Type Journal Article

Author S. Nakajima

Author M. Sugiyama

Abstract Learning from positive and unlabeled (PU) data is an important problem in various applications. Most of the recent approaches for PU classification assume that the class-prior (the ratio of positive samples) in the training unlabeled dataset is identical to that of the test data, which does not hold in many practical cases. In addition, we usually do not know the class-priors of the training and test data, thus we have no clue on how to train a classifier without them. To address these problems, we propose a novel PU classification method based on density ratio estimation. A notable advantage of our proposed method is that it does not require the class-priors in the training phase; class-prior shift is incorporated only in the test phase. We theoretically justify our proposed method and experimentally demonstrate its effectiveness. © 2022, The Author(s), under exclusive licence to Springer Science+Business Media LLC, part of Springer Nature.

Positive-Unlabeled Hyperspectral Image Classification using nnPU Loss and Masked Autoencoder

Item Type Conference Paper

Author O.S. Melashchenko

Abstract Hyperspectral image classification has seen significant progress with deep learning, especially CNN- and Transformer-based architectures that capture spectral-spatial relationships. However, two fundamental challenges remain: (i) the scarcity of labeled data due to the cost of pixel-level annotation, and (ii) the difficulty of fully utilizing abundant unlabeled data without overfitting. Positive-unlabeled learning addresses these issues by exploiting unlabeled data alongside a small set of positive labels, but its accuracy depends heavily on the quality of the unlabeled samples and the precision of class prior estimation. In this work, we investigate the case where the prior is known and focus on improving representation learning within positive-unlabeled frameworks. We propose a joint masked autoencoder and positive-unlabeled learning method for hyperspectral image classification. Experimental results show that our approach achieves consistent gains over standard positive-unlabeled baselines under scenarios with limited labeled data. These results highlight the effectiveness of combining masked autoencoder-based representations with positive-unlabeled classification. Positive-unlabeled learning for anomaly detection based on dual-branch generative adversarial networks

Item Type Journal Article

Author Q. Wei

Author A. Li

Author J. Hu

Author C. Han

Author Y. Chi

Author Y. Shi

Abstract Anomaly detection under positive-unlabeled (PU) learning remains challenging as only a few anomalies are labeled, whereas the majority of data remain unlabeled and may be contaminated by unknown anomalies. Existing PU learning approaches often rely on imprecise class-prior estimation or biased synthetic sample generation, potentially leading to unstable optimization and degraded detection performance. To mitigate these limitations, we propose PUGANomaly, a novel PU learning method for anomaly detection based on dual-branch generative adversarial networks (GANs). PUGANomaly integrates anomaly detection and PU learning within a unified architecture. By incorporating a self-training mechanism and a joint anomaly scoring strategy, PUGANomaly iteratively refines pseudo-negative samples and model parameters from anomaly similarity and normal dissimilarity perspectives. Furthermore, we design a set of PU-specific loss functions to explicitly enforce increased separation between normal and anomalous representations. To further strengthen discriminative capability, an auxiliary classifier is incorporated to learn the decision boundary between labeled anomalies and pseudo-normal samples, and the outputs are subsequently fused with reconstruction-based anomaly scores through an ensemble learning module. Extensive experiments conducted on the MNIST, FashionMNIST, and Alzheimer datasets demonstrate that PUGANomaly consistently and statistically outperforms state-of-the-art GAN-based PU learning models on anomaly detection tasks, achieving superior detection accuracy and robustness under limited supervision. © 2026 Elsevier B.V.

Positive-Unlabeled Learning With Label Distribution Alignment

Item Type Journal Article

Author Y. Jiang

Author Z. Yang

Author P. Wen

Author X. Cao

Author Q. Huang

Abstract Positive-Unlabeled (PU) data arise frequently in a wide range of fields such as medical diagnosis, anomaly analysis and personalized advertising. The absence of any known negative labels makes it very challenging to learn binary classifiers from such data. Many state-of-the-art methods reformulate the original classification risk with individual risks over positive and unlabeled data, and explicitly minimize the risk of classifying unlabeled data as negative. This, however, usually leads to classifiers with a bias toward negative predictions, i.e., they tend to recognize most unlabeled data as negative. In this paper, we propose a label distribution alignment formulation for PU learning to alleviate this issue. Specifically, we align the distribution of predicted labels with the ground-truth, which is constant for a given class prior. In this way, the proportion of samples predicted as negative is explicitly controlled from a global perspective, and thus the bias toward negative predictions could be intrinsically eliminated. On top of this, we further introduce the idea of functional margins to enhance the model's discriminability, and derive a margin-based learning framework named Positive-Unlabeled learning with Label Distribution Alignment (PULDA). This framework is also combined with the class prior

estimation process for practical scenarios, and theoretically supported by a generalization analysis. Moreover, a stochastic mini-batch optimization algorithm based on the exponential moving average strategy is tailored for this problem with a convergence guarantee. Finally, comprehensive empirical results demonstrate the effectiveness of the proposed method. © 1979-2012 IEEE.

Positive-Unlabeled Learning-Based Hybrid Deep Network for Intelligent Fault Detection

Item Type Journal Article

Author M. Qian

Author Y.-F. Li

Author T. Han

Abstract Intelligent fault detection methods based on deep learning have been developed rapidly in recent years. However, most of these methods are based on supervised learning which requires a fully labeled training set. It is difficult to obtain massive labeled samples in real applications incredibly accurately labeled fault samples from an operating system. The lack of labels and label noise becomes a great challenge for fault detection. To tackle this problem, in this article, we propose a positive-unlabeled learning based hybrid network (PUHN). It only needs part of the normal operating samples to be labeled. All other samples (including the rest of the normal samples and all fault samples) are unlabeled, which greatly reduces the labeling cost. PUHN consists of three modules: a nonnegative risk positive-unlabeled (PU) network for training the classifier, a feature extraction module, and a clustering layer for improving data separability and estimating the class priors of PU learning. The three are optimized as a whole and the corresponding optimization strategy is designed. The monitoring data of 24 wind turbines are used to verify the effectiveness and robustness of the proposed method. The experimental results indicate that the proposed method is superior to the benchmark methods, and the performance is significantly better than the supervised learning method when there exists label noise. © 2005-2012 IEEE.

PostgreSQL anomalous query detector

Item Type Conference Paper

Author B. Shebaro

Author A. Sallam

Author A. Kamra

Author E. Bertino

Abstract We propose to demonstrate the design, implementation, and the capabilities of an anomaly detection (AD) system integrated with a relational database management system (DBMS). Our AD system is trained by extracting relevant features from the parse-tree representation of the SQL commands, and then uses the DBMS roles as the classes for the bayesian classifier. In the detection phase, the maximum apriori probability role is chosen by the classifier which, if not matching the role associated with the SQL command, raises an alarm. We have implemented such system in the PostgreSQL DBMS, integrated with the statistics collection and the query processing mechanism of the DBMS. During the demonstration, our audience will be given the choice of training our system using either synthetic role-based SQL query traces based on probability sampling, or by entering their own set of training queries. In the subsequent detection mode, the audience can test the detection capabilities of the system by submitting arbitrary SQL commands. We will also allow the audience to generate arbitrary work loads to measure the overhead of the training phase and the detection phase of our AD mechanism on the performance of the DBMS. © 2013 Authors.

Power control strategy for distributed multiple-hypothesis detection

Item Type Journal Article

Author H.-S. Kim

Author N.A. Goodman

Abstract We introduce a local-channel power control strategy applicable to multiple-hypothesis distributed detection systems communicating over slow-fading orthogonal multiple-access channels. In earlier work, it was demonstrated that performance could be improved by adjusting transmit power to maximize the J-divergence measure of a binary detection system. The local power control strategy introduced here further improves performance by exploiting a priori probabilities and local sensor statistics. Moreover, the local power optimization can be combined with additional power control based on the state of the propagation channel. We extend the optimization to systems performing multiple-hypothesis detection, and evaluate outage probability for these systems. Various numerical results are shown. © 2010 IEEE.

Practical Uncertainty Quantification in Orbital Mechanics

Item Type Journal Article

Author M. Vasile

Abstract The chapter provides an overview of methods to quantify uncertainty in orbital mechanics. It also provides an initial classification of these methods with particular attention to whether the quantification method requires a knowledge of the system model or not. For some methods the chapter provides applications examples and numerical comparisons on selected test cases. © 2019, Springer Nature Switzerland AG.

Pre- and post-harvest spectral estimation of carnosic acid and rosmarinic acid in rosemary

Item Type Journal Article**Author** A. Mishra**Author** A. Krief**Author** M.M. Sahoo**Author** A. Schachter**Author** I. Gonda**Author** N. Dudai**Author** T. Trigano**Author** I. Herrmann

Abstract Rosemary extracts, including carnosic and rosmarinic acids (CA and RA, respectively), are known for their antimicrobial and antioxidant capabilities. Traditional quantification methods of CA and RA (later on called selected phytochemicals) are often destructive and time-consuming. This study presents a spectral, non-destructive, and time-efficient approach for estimating selected phytochemicals in pre- and post-harvest stages. We acquired spectral data from field-grown rosemary plants, dry leaves, and powder as well as UAV-borne hyperspectral imagery. The analysis included a transformation sequence (second derivative, Yeo–Johnson, and standardization), followed by partial least squares regression (PLSR). To mimic real-life scenarios, we investigated a training–testing strategy denoted by “leave-one-day-out”, systematically excluding each day's data from training. For CA estimation, the PLSR model achieved a coefficient of determination (R^2) of 0.75 with a relative root mean square error (RRMSE) of 10.42% at the canopy level, 0.80 (RRMSE: 8.91%) for dry leaves, and 0.76 (RRMSE: 9.09%) for powder. RA estimation was challenging at the canopy level with an R^2 of 0.52 (RRMSE: 13.42%), but improved in post-harvest samples, reaching R^2 of 0.79 (RRMSE: 10.0%) for dry leaves and 0.75 (RRMSE: 9.78%) for powder. These results demonstrated the efficiency of the proposed approach. It offers a reliable alternative to traditional methods, with potential applications in agriculture and post-harvest industry. © 2026 The Authors

Abstract Background: Scalable identification of patients with post-acute sequelae of COVID-19 (PASC) is challenging due to a lack of reproducible precision phenotyping algorithms, which has led to suboptimal accuracy, demographic biases, and underestimation of the PASC. Methods: In a retrospective case-control study, we

developed a precision phenotyping algorithm for identifying cohorts of patients with PASC. We used longitudinal electronic health records data from over 295,000 patients from 14 hospitals and 20 community health centers in Massachusetts. The algorithm employs an attention mechanism to simultaneously exclude sequelae that prior conditions can explain and include infection-associated chronic conditions. We performed independent chart reviews to tune and validate the algorithm. Findings: The PASC phenotyping algorithm improves precision and prevalence estimation and reduces bias in identifying PASC cohorts compared to the ICD-10-CM code U09.9. The algorithm identified a cohort of over 24,000 patients with 79.9% precision. Our estimated prevalence of PASC was 22.8%, which is close to the national estimates for the region. We also provide in-depth analyses, encompassing identified lingering effects by organ, comorbidity profiles, and temporal differences in the risk of PASC. Conclusions: PASC precision phenotyping boasts superior precision and prevalence estimation while exhibiting less bias in identifying patients with PASC. The cohort derived from this algorithm will serve as a springboard for delving into the genetic, metabolomic, and clinical intricacies of PASC, surmounting the constraints of prior PASC cohort studies. Funding: This research was funded by the US National Institute of Allergy and Infectious Diseases (NIAID). © 2024 The Author(s)

Precision-Recall Operating Characteristic (P-ROC) curves in imprecise environments

Item Type	Conference Paper
Author	T.C.W. Landgrebe
Author	P. Paclik
Author	R.P.W. Duin
Author	A.P. Bradley
Abstract	Traditionally, machine learning algorithms have been evaluated in applications where assumptions can be reliably made about class priors and/or misclassification costs. In this paper, we consider the case of imprecise environments, where little may be known about these factors and they may well vary significantly when the system is applied. Specifically, the use of precision-recall analysis is investigated and compared to the more well known performance measures such as error-rate and the receiver operating characteristic (ROC). We argue that while ROC analysis is invariant to variations in class priors, this invariance in fact hides an important factor of the evaluation in imprecise environments. Therefore, we develop a generalised precision-recall analysis methodology in which variation due to prior class probabilities is incorporated into a multi-way analysis of variance (ANOVA). The increased sensitivity and reliability of this approach is demonstrated in a remote sensing application. © 2006 IEEE.

Abstract Deoxynivalenol (DON) is a major hazardous component in wheat kernels infected by Fusarium head blight. Given the lack of both reliable and cost-effective quantification methods, this study aims to use Fourier-transform infrared spectroscopy with attenuated total reflectance (ATR-FTIR) for predicting DON concentrations. Four machine learning models, including eXtreme Gradient Boosting (XGBoost), Random Forest (RF), Tabular Prior-data Fitted Network (TabPFN), and Categorical Boosting (CatBoost), were firstly developed using key spectral features selected by recursive feature elimination (RFE). TabPFN model outperformed others in quantitative

prediction, achieving a coefficient of determination (R^2) of 0.86 on hold-out test set. SHapley Additive exPlanations (SHAP) were firstly applied to enhance model interpretability and transparency, identifying wavenumbers at 996 cm^{-1} , 1083 cm^{-1} , 1135 cm^{-1} , and 1574 cm^{-1} as having higher influence on model performance. For binary classification of DON levels (<1 or ≥ 1 mg/kg), Catboost model achieved superior results, yielding a recall of 0.91, accuracy of 0.88, and an F2 score of 0.91. This study highlights the effectiveness of machine learning based analysis of FTIR spectra. Furthermore, the proposed approach herein could be a feasible way for monitoring DON levels in wheat flour, with potential applications at both laboratory and industrial scales to ensure food safety. © 2026 The Authors

Predicting cognitive decline with deep learning of brain metabolism and amyloid imaging

Item Type Journal Article

Author H. Choi

Author K.H. Jin

Abstract For effective treatment of Alzheimer's disease (AD), it is important to identify subjects who are most likely to exhibit rapid cognitive decline. We aimed to develop an automatic image interpretation system based on a deep convolutional neural network (CNN) which can accurately predict future cognitive decline in mild cognitive impairment (MCI) patients using flurodeoxyglucose and florbetapir positron emission tomography (PET). PET images of 139 patients with AD, 171 patients with MCI and 182 normal subjects obtained from Alzheimer's Disease Neuroimaging Initiative database were used. Deep CNN was trained using 3-dimensional PET volumes of AD and normal controls as inputs. Manually defined image feature extraction such as quantification using predefined region-of-interests was unnecessary for our approach. Furthermore, it used minimally processed images without spatial normalization which has been commonly used in conventional quantitative analyses. Cognitive outcome of MCI subjects was predicted using this network. The prediction accuracy of the conversion of mild cognitive impairment to AD was compared with the conventional feature-based quantification approach. Accuracy of prediction (84.2%) for conversion to AD in MCI patients outperformed conventional feature-based quantification approaches. ROC analyses revealed that performance of CNN-based approach was significantly higher than that of the conventional quantification methods ($p < 0.05$). Output scores of the network were strongly correlated with the longitudinal change in cognitive measurements ($p < 0.05$). These results show the feasibility of deep learning as a practical tool for developing predictive neuroimaging biomarker. © 2018 Elsevier B.V.

Author S. Xu
Author W. Liao
Author C. Tang
Author X. Zhang

Abstract Floor heave is a common defect in mountainous tunnels. It is critical but challenging to predict the risk of floor heave, as traditional methods often fail to characterize this phenomenon effectively. This study proposes a data-driven approach utilizing a support vector machine (SVM) optimized by the sparrow search algorithm (SSA) to address the issue. The model was developed and validated using a dataset collected from 100 tunnels. Shapley value analysis was conducted to identify the key features influencing floor heave defects. Moreover, a committee-based uncertainty quantification method is presented to evaluate the reliability of each prediction. The results show that: (1) Data feature engineering and SSA play pivotal roles in expediting the convergence of the SVM model. (2) Groundwater and high in situ stress are key factors contributing to tunnel floor heave. (3) In comparison to backpropagation (BP) neural networks, the SSA-SVM demonstrates superior robustness in handling imperfect and limited data. (4) The committee-based uncertainty quantification method is proven effective to evaluate the trustworthiness of each prediction. This data-driven surrogate model offers an effective strategy for understanding the factors that impact tunnel floor defects and accurately predicting tunnel floor heave deformation. © 2025 Institute of Rock and Soil Mechanics, Chinese Academy of Sciences

Predicting incomplete gene microarray data with the use of supervised learning algorithms

Item Type Journal Article

Author B. Twala

Author M. Phorah

Abstract Motivation: With the wealth of sequence data and the huge amount of data generated from molecular technologies, the issue of gene classification/ prediction has become a central challenge in the field of microarray data analysis. This has led to the application of many well-established supervised learning (SL) algorithms in an attempt to provide more accurate and automatic diagnosis class (cancer/non cancer) prediction. Virtually all research on SL addresses the task of learning to classify complete domain instances. However, in some research situations we often have to classify instances given incomplete vectors, which can affect the predictive accuracy of learned classifiers. The task of learning an accurate incomplete data classifier from instances raises a number of new issues some of which have not been properly addressed by bioinformatics research. Thus, an effective missing value estimation method is required for improving predictive accuracy. Results: The essence of the approach is the proposal that prediction using supervised learning can be improved in probabilistic terms given incomplete microarray data. This imputation approach is based on the a priori probability of each value determined from the instances at that node of a decision tree (PDT) that have specified values. The proposed approach exploits the total probability and Bayes' theorems and it has three versions. We evaluate our approach with other supervised learning techniques including C5.0, classification and regression trees (CART), k-nearest neighbour (k-NN), linear discrimination (LD) naïve Bayes classifier (NBC), Repeated Incremental Pruning to Produce Error Reduction (RIPPER) and support vector machines (SVMs), from the point of view of their effect or tolerance of incomplete test data. Eight cancer related gene expression datasets are utilized for this task. Experimental results are provided to illustrate the efficiency and the robustness of the proposed algorithm. © 2010 Elsevier B.V. All rights reserved.

Predicting mechanical properties of low-alloy steels using features extracted from Electron Backscatter Diffraction characterization

Item Type Journal Article**Author** Y. Li**Author** J. Zhao**Author** X. Li**Author** Z. Xing**Author** Q. Duan**Author** X. Liang**Author** X. Wang

Abstract Machine learning (ML) approaches have recently been increasingly employed to establish quantitative relationships between material composition, processing, microstructure, and properties. However, the complexities of microstructure pose challenges for straightforward modeling, thereby complicating research efforts. This study introduces a series of multi-parametric quantification methods based on Electron Backscatter Diffraction (EBSD) data tailored to the microstructural characteristics of low-alloy steels. These methods include quantification of boundary densities across various misorientation angles, distinct types of boundaries, and geometrically necessary dislocation densities. Through thermomechanical simulation and micro-tensile testing of low-alloy steels, data on yield and ultimate tensile

strengths were obtained, alongside EBSD-based extraction of microstructure characteristics. Several ML methods, including Random Forest (RF), Gradient Boosting Decision Trees (GBDT), and Extreme Gradient Boosting (XGBoost), were utilized to predict yield strength (YS) and ultimate tensile strength (UTS) using the aforementioned microstructural features. The GBDT model outperformed other algorithms, demonstrating high accuracy in predicting YS, UTS, and elongation. The model achieved an Mean Squared Error (MSE) of 972.18, an Mean Absolute Error (MAE) of 24.75 and an Coefficient of Determination (R2) of 0.864 for YS, and an MSE of 812.28, an MAE of 22.87 and an R2 of 0.823 for UTS. These results confirm GBDT's effectiveness in predicting mechanical properties from microstructural data. This successful integration of ML with multi-parametric description microstructural features underscores its potential in facilitating material design and development processes. © 2024 The Authors

Predicting protein functions using positive-unlabeled ranking with ontology-based priors

Item Type Journal Article

Author F. Zhapa-Camacho

Author Z. Tang

Author M. Kulmanov

Author R. Hoehndorf

Abstract Automated protein function prediction is a crucial and widely studied problem in bioinformatics. Computationally, protein function is a multilabel classification problem where only positive samples are defined and there is a large number of unlabeled annotations. Most existing methods rely on the assumption that the unlabeled set of protein function annotations are negatives, inducing the false negative issue, where potential positive samples are trained as negatives. We introduce a novel approach named PU-GO, wherein we address function prediction as a positive-unlabeled ranking problem. We apply empirical risk minimization, i.e. we minimize the classification risk of a classifier where class priors are obtained from the Gene Ontology hierarchical structure. We show that our approach is more robust than other state-of-the-art methods on similarity-based and time-based benchmark datasets. © The Author(s) 2024. Published by Oxford University Press.

Predicting short-term interruptions of antiretroviral therapy from summary adherence data: Development and test of a probability model

Item Type Journal Article

Author R. Gross

Abstract Antiretroviral therapy (ART) for HIV is vulnerable to unplanned treatment interruptions—consecutively missed doses over a series of days—which can result in virologic rebound. Yet clinicians lack a simple, valid method for estimating the risk of interruptions. If the likelihood of ART interruption could be derived from a convenient-to-gather summary measure of medication adherence, it might be a valuable tool for both clinical decision-making and research. We constructed an a priori probability model of ART interruption based on average adherence and tested its predictions using data collected on 185 HIV-infected, treatment-naïve individuals over the first 90 days of ART in a prospective cohort study in Mbarara, Uganda. The outcome of interest was the presence or absence of a treatment gap, defined as >72 hours without a dose. Using the pre-determined value of 0.50 probability as the cut point for predicting an interruption, the classification accuracy of the model was 73% (95% CI = 66%– 79%), the specificity was 87% (95% CI = 79%– 93%), and the sensitivity was 59% (95% CI = 48%– 69%). Overall model performance was satisfactory, with an area under the receiver operator characteristic curve (AUROC) of 0.85 (95% CI = 0.80–0.91) and Brier score of 0.20. The study serves as proof-of-concept that the probability model can accurately differentiate patients on the continuum of risk for short-term ART interruptions using a summary measure of adherence. The model may also aid in the design of targeted interventions. © This is an open access article, free of all copyright, and may be freely reproduced, distributed, transmitted, modified, built upon, or otherwise used by anyone for any lawful purpose. Predicting the cytotoxicity of nanomaterials through explainable, extreme gradient boosting

Item Type Journal Article

Author A. Conti

Author L. Campagnolo

Author S. Diciotti

Author A. Pietroiusti

Author N. Toschi

Abstract Nanoparticles (NPs) are a wide class of materials currently used in several industrial and biomedical applications. Due to their small size (1-100 nm), NPs can easily enter the human body, inducing tissue damage. NP toxicity depends on physical and

chemical NP properties (e.g., size, charge and surface area) in ways and magnitudes that are still unknown. We assess the average as well as the individual importance of NP atomic descriptors, along with chemical properties and experimental conditions, in determining cytotoxicity endpoints for several nanomaterials. We employ a multicenter cytotoxicity nanomaterial database (12 different materials with first and second dimensions ranging between 2.70 and 81.2 nm and between 4.10 and 4048 nm, respectively). We develop a regressor model based on extreme gradient boosting with hyperparameter optimization. We employ Shapley additive explanations to obtain good cytotoxicity prediction performance. Model performances are quantified as statistically significant Spearman correlations between the true and predicted values, ranging from 0.5 to 0.7. Our results show that i) size in situ and surface areas larger than 200 nm and 50 m²/g, respectively, ii) primary particles smaller than 20 nm; iii) irregular (i.e., not spherical) shapes and iv) positive Z-potentials contribute the most to the prediction of NP cytotoxicity, especially if lactate dehydrogenase (LDH) assays are employed for short experimental times. These results were moderately stable across toxicity endpoints, although some degree of variability emerged across dose quantification methods, confirming the complexity of nano-bio interactions and the need for large, systematic experimental characterization to reach a safer-by-design approach. © 2022 Informa UK Limited, trading as Taylor & Francis Group.

Prediction Accuracy & Reliability: Classification and Object Localization Under Distribution Shift

Item Type Journal Article

Author F. Diet

Author M. Kassem Sbeyti

Author M. Karg

Abstract Natural distribution shiftDistribution shift causes a performance deterioration for the visual perception computed by convolutional neural networks (CNNs). This can lead to safety-critical situations, when deploying CNNs to real-world traffic data. To facilitate a quantitative analysis of this deterioration, this work addresses: (1) investigating the effect of natural distribution shiftDistribution shift and weather augmentations on the performance of detection and confidence estimation, (2) evaluating model accuracy and confidence prediction for both object classificationClassification and its localization, and (3) benchmarking two common uncertaintyUncertainty quantification methods - EnsemblesEnsemble and compute-efficient variants of Monte-Carlo (MC) DropoutDropout. For this purpose, a novel dataset has been curated from publicly available autonomous driving datasets. The in-distribution (ID) data is based on cutouts of individual objects, for which both class and bounding box annotations are available. The six distribution-shift datasets cover adverse weather scenarios, simulated rain and fog, corner cases, and out-of-distribution data. A granular analysis of CNNs under distribution shiftDistribution shift allows to quantize the impact of different types of shifts on both, task performance and confidence estimation. Our novel key findings are: ConvNeXt-Tiny is more robust to distribution shiftDistribution shift than EfficientNet-B0; heavy rain degrades classificationClassification accuracy stronger than localization, whereas heavy fog has the opposite effect; integrating MC-Dropout into selected layers only has the potential to enhance task performance and confidence estimation, with the identification of these layers depending on the type of distribution shiftDistribution shift and the considered task. © The Author(s), under exclusive license to Springer Nature Switzerland AG 2024.

Prediction and outlier detection in classification problems

Item Type Journal Article

Author L. Guan

Author R. Tibshirani

Abstract We consider the multi-class classification problem when the training data and the out-of-sample test data may have different distributions and propose a method called BCOPS (balanced and conformal optimized prediction sets). BCOPS constructs a prediction set $C(x)$ as a subset of class labels, possibly empty. It tries to optimize the out-of-sample performance, aiming to include the correct class and to detect outliers x as often as possible. BCOPS returns no prediction (corresponding to $C(x)$ equal to the empty set) if it infers x to be an outlier. The proposed method combines supervised learning algorithms with conformal prediction to minimize a misclassification loss averaged over the out-of-sample distribution. The constructed prediction sets have a finite sample coverage guarantee without distributional assumptions. We also propose a method to estimate the outlier detection rate of a given procedure. We prove asymptotic consistency and optimality of our proposals under suitable assumptions and illustrate our methods on real data examples. © 2022 The Authors. Prediction for Tunnelling-Induced Ground Settlement in Multilayered Soils: An Improved Gradient Boosting Approach

Item Type Journal Article**Author** H. An**Author** Y. Chen**Author** J. Lei**Author** H. Luo**Author** E.J. Chen

Abstract During the construction of a shield tunnel, it will disturb the surrounding ground and affect the use and structural safety of buildings around the tunnel. The geometric parameters of the tunnel, the operating parameters of the shield machine, and the geological parameters will affect the degree of disturbance. However, the existing theories and models are difficult to comprehensively consider the interaction of these factors, and it is difficult to accurately predict the response of the formation to solve the above problems. The research is based on the machine learning algorithm to establish a prediction model of stratum settlement caused by shield tunneling, which provides a new idea for real time prediction of the ground response caused by shield tunneling and risk reduction. The main results of this research are as follows: (1) propose a novel quantification method for geological parameters that can comprehensively consider the physical and mechanical properties of the rock, soil layers, and the geometric characteristics of depth and thickness and (2) establish a more robust proxy model and use the k-fold cross-validation method to enhance its performance. Prediction Interval in Renewable Energy Forecasting: A Comprehensive Review of Uncertainty Quantification Methods

Item Type Journal Article

Author N. Sakib

Author M.A. Hosen

Author B. Khan

Author B. Gunn

Author M. Johnstone

Abstract Robust and reliable forecasting of renewable energy generation is essential for managing grid stability, optimising energy resources, and meeting global climate targets, such as the European Union's goal of achieving Net-Zero greenhouse gas emissions by 2050. Renewable energy sources, including solar, wind, and tidal, are inherently variable and difficult to predict, while hydro is comparatively more stable but still subject to seasonal and climatic fluctuations. This variability poses significant challenges to grid operators and policymakers striving to integrate more renewable energy into the power system. Prediction Interval (PI), which quantifies uncertainty by providing a probabilistic range of potential outcomes, offer a solution to this problem by enhancing the reliability and accuracy of renewable energy forecasts. This paper reviews the methodologies for estimating prediction interval, including statistical, machine learning, and deep learning approaches, and demonstrates how these techniques can address the key challenges in renewable energy forecasting. By offering a structured comparison of prediction interval estimation methods across different renewable energy sectors, the paper highlights their potential to reduce uncertainty, improve decision-making for grid integration,

and assist policymakers in developing strategies to mitigate risks from energy variability. Moreover, the review identifies critical gaps in current research and proposes future directions that could further refine prediction interval estimation methods for greater accuracy and applicability. The insights provided in this review can aid scientists, engineers, and decision-makers in advancing renewable energy forecasting techniques, thereby accelerating the transition toward a more sustainable and resilient energy system. © 2013 IEEE.

Prediction of driver alertness levels on mountain roads using machine learning models: A naturalistic driving study in China

Item Type Journal Article

Author T. Liu

Author D. Xie

Author T. Liu

Author J. Shan

Author C. Tang

Abstract Objective: A method for evaluating driver alertness on mountain roads was developed to enhance dynamic safety monitoring in high-risk sections. An indicator system integrating human and environmental factors was established, with 13 variables used for alertness classification and 17 initial variables applied for quantification. Methods: Field tests were conducted in Guizhou, China, where data on drivers' heart rates, eye movements, and demographics were collected. Kernel principal component analysis (KPCA) was employed to extract four representative factors from 13 driving-related indicators. K-means clustering was employed to categorize drivers into high- and low-alertness groups. Logistic regression scoring, XGBoost, and Tabular Prior-Data Fitted Network (TabPFN) models were developed to assess driver alertness probabilities. Results: Superior performance was demonstrated by the XGBoost model, achieving an area under the receiver operating characteristic curve (AUC) value of 0.97 compared with 0.80 for logistic regression scoring model, indicating improved classification accuracy and robustness. TabPFN further enhanced performance, yielding the highest results (AUC: 0.98; KS: 0.85; F1: 0.90), confirming its robustness and adaptability in small-sample, high-dimensional data settings. Conclusion: Driver alertness levels were effectively quantified by integrating human and environmental factors. TabPFN model was found to be more effective than logistic regression scoring and XGBoost, making it the preferred approach for monitoring driver alertness on mountain roads. © 2025 Taylor & Francis Group, LLC.

Prediction of Tail Water Level under the Influence of Backwater Effect Based on Deep Learning Models: A Case Study in the Xiangjiaba Hydropower Station

Item Type Journal Article

Author S. Zhang

Author S. Xie

Author Y. Wang

Author Y. Xu

Author Z. Zhang

Author B. Jia

Abstract Accurate forecasting of the tail water level (TWL) is of great importance for the safe and economic operation of hydropower stations. The prediction accuracy is significantly influenced by the backwater effect of downstream tributaries and the operation of adjacent hydropower stations, but the explicit quantification method of the backwater effect is lacking. In this study, a deep-learning-model-based forecasting method for TWL predictions under the backwater effect is developed and applied in the Xiangjiaba (XJB) hydropower station, which is influenced by the backwater effect of downstream tributaries, including the Hengjiang River (HJR) and the Minjiang River (MJR). Firstly, the random forest algorithm was used to analyze the influence of HJR and MJR flows with different lag times on the TWL prediction error of the XJB hydropower station. The results show that the time lags of the backwater effect of HJR and MJR run offs on the TWL of the XJB are 5~7 h and 1~2 h, respectively. Then, the run off thresholds of the HJR and MJR for impacting the TWL of the XJB station are obtained through scenario comparison, and the results show that the run off thresholds of the HJR and the MJR are 700 m³/s and 7000 m³/s, respectively. Finally, based on the analysis of the time lag and the threshold of the backwater effect, a deep learning model (LSTM)-based TWL forecasting method is established and applied to predict the TWL of the XJB station. The results show that the forecasting model has a good predictive performance, with 98.22% of absolute errors less than 20 cm. The mean absolute error over the validation dataset is 5.27 cm, and the maximum absolute error is 63.35 cm. Compared with the LSTM-based prediction model without considering the backwater effect, the mean absolute error decreased by 31%, and the maximum absolute error decreased by 71%. © 2023 by the authors.

Author T. Jacob

Abstract Objective: To evaluate potential predictive factors associated with success or failure of incompetent perforating veins (IPVs) treated with radio-frequency stylet (RFS). Methods: Over the last 12 months in this observational study, 38 consecutive patients with various degrees of venous insufficiency and IPVs underwent 48 office-based radio-frequency ablation procedures (1 - C 3; 7 - C 4; 10 - C 5; 30 - C 6) in 44 limbs. There were 21 females and 17 males with a mean age of 67 ± 17 years (38-93 years) who had a total of 93 IPVs (40 calf; 53 ankle). Eighteen patients (47%) had ipsilateral great saphenous vein (GSV) radio-frequency closures performed prior to current procedure. The venous flow pattern was classified by spectral waveform analysis as "normal" (spontaneous with respiratory phasicity) in 33 patients and "pulsatile" (with bidirectional cardiac phasicity) in five patients. Follow-up duplex scans were performed from 3 to 7 days postprocedure. Statistical analyses were performed for determining correlation between the various factors such as, age, pulsatile flow, CEAP class, prior GSV ablation, vein diameter, reflux, and patency. Results: The mean number of ablated IPVs was 1.94 ± 0.38 ranging from 1-3. Immediate success rate was 88% (82 cases, 32 patients). IPVs had a duplex measured mean diameter of 3.8 ± 1.1 mm (2-6.6 mm). Eleven IPVs remained patent in six patients. There was no significant difference between the patent and the obliterated IPV groups concerning age ($P = 0.75$), prior GSV ablation ($P = .19$), IPV diameter ($P = .08$) and CEAP classification. Conversely, four of the five procedures (80%) performed in patients with "pulsatile" venous flow failed, while only two of the remaining 43 procedures (4.7%) in patients with "normal" venous flow failed ($P < .001$). Conclusion: These data show that a pulsatile venous flow pattern is a significant predictor of failure following RFS for IPVs. © 2009 Society for Vascular Surgery.

Abstract Aims: With recurrence rates up to 50% after pulmonary vein isolation (PVI) in persistent atrial fibrillation (AF), predictive tools to improve patient selection are needed. Patient selection based on left atrial late gadolinium enhancement (LGE) cardiovascular magnetic resonance (CMR) has been proposed previously (UTAH-classification). However, this approach has not been widely established, in part owed to the lack of standardization of the LGE quantification method. We have recently established a standardized LGE-CMR method enabling reproducible LGE-quantification. Here, the ability of this method to predict outcome after PVI was evaluated. Methods and results: This dual-centre study (n = 219) consists of a prospective derivation cohort (n = 37, all persistent AF) and an external validation cohort (n = 182; 66 persistent, 116 paroxysmal AF). All patients received an LGE-CMR prior to first-Time PVI-only ablation. LGE was quantified based on the signal-intensity-ratio relative to the blood pool, applying a uniform LGE-defining threshold of >1.2. In patients with persistent AF in the derivation cohort, left atrial LGE-extent above a cut-off value of 12% was found to best predict relevant low-voltage substrate (≥ 2 cm two with <0.5 mV during sinus rhythm) and arrhythmia-free survival 12 months post-PVI. When applied to the external validation cohort, this cut-off value was also predictive of arrhythmia-free survival for both, the total cohort and the subgroup with persistent AF (LGE < 12%: 80% and 76%; LGE > 12%: 55% and 44%; P = 0.007 and P = 0.029, respectively). Conclusion: This dual-centre study established and validated a standardized, reproducible LGE-CMR method discriminating PVI responders from non-responders, which may improve choice of therapeutic approach or ablation strategy for patients with persistent AF. © 2022 The Author(s). Abstract Objective: Pregnancies in patients with adult congenital heart disease (ACHD) are often complicated. We aimed to highlight the nature and the rate of these complications in a single-center patient population. Methods: We retrospectively studied all the pregnancies of women who presented on an outpatient basis, and all pregnancies were reviewed for maternal and fetal outcomes. Results: Of 117 pregnancies from 52 ACHD patients (age at pregnancy 28.3 ± 6.6 years), 10 were therapeutically aborted. A proportion of 41.1% of the remaining 107 pregnancies were complicated either with cardiac (3.7%), obstetric (15.0%), or fetal/neonatal (11.2%) adverse events or with spontaneous abortion (17.8%). Hospitalization during pregnancy was required in 10 patients. Elective cesarean sections were initially planned for 31% of the 87 pregnancies, which were finally completed, while 8% required an emergency cesarean section, mostly for obstetric reasons. NYHA class deterioration after pregnancy was detected in 9.3% of our cohort. Modified WHO class III/IV, prior medication use, and higher body mass index (BMI) were related to cardiac complications during pregnancy or NYHA deterioration. Conclusion: Pregnancies in ACHD patients are at high risk for complications. Advanced modified WHO class, prior medication use, and high BMI were related to adverse cardiac events. © 2017 Hellenic Society of Cardiology

Premonitory symptoms in migraine: a systematic review and meta-analysis of observational studies reporting prevalence or relative frequency

Item Type Journal Article

Abstract Background: Observational studies on the prevalence of premonitory symptoms in people with migraine, preceding the headache pain (or aura) phase, have shown conflicting results. We conducted a systematic review and meta-analysis to estimate the prevalence, and relative frequency among clinic populations, of premonitory symptoms in people with migraine, overall and of the multifarious individual symptoms, and to review the methodologies used to assess them. Methods: We searched PubMed and Embase for studies published from database inception until 31st of May 2022. Two investigators independently screened titles, abstracts, and full texts. We retrieved observational studies that reported the prevalence/relative frequency of one or more premonitory symptoms in people with migraine. Two investigators independently extracted data and assessed risk of bias. Results were pooled using random-effects meta-analysis. Our main outcomes were the percentage of people with migraine who experienced at least one premonitory symptom and the percentages who experienced different individual premonitory symptoms. To describe our outcomes, we used the terms prevalence for data from population-based samples and relative frequency for data from clinic-based samples. We also descriptively and critically assessed the methodologies used to assess these symptoms. Results: The pooled estimated prevalence in population-based studies of at least one premonitory symptom was 29% (95% CI: 8–63; I² 99%) and the corresponding pooled estimated relative frequency in clinic-based studies was 66% (95% CI: 45–82; I² 99%). The data from clinic-based studies only supported meta-analysis of 11 of 96 individual symptoms, with relative frequency estimates ranging from 11 to 49%. Risk of bias was determined as high in 20 studies, moderate in seven, and low in two. Conclusions: The substantial between-study heterogeneity demands cautious interpretation of our estimates. Studies showed wide methodological variations, and many lacked rigor. Overall, the evidence was insufficient to support reliable prevalence estimation or characterization of premonitory symptoms. More data are needed, of better quality, to confirm the existence of a distinctive premonitory phase of migraine, and its features. Methodological guidelines based on expert consensus are a prerequisite. © 2022, The Author(s).

Abstract In the last few decades, many new paramyxoviruses have been discovered, causing diverse, mostly respiratory diseases in animals and humans. The porcine parainfluenza virus 1 (PPIV-1, species Porcine respirovirus 1), which has been reported in many countries worldwide, was found in both healthy and clinically ill pigs showing respiratory signs. Here, we report the expected prevalence and genetic diversity of PPIV-1 in Hungarian pig herds and the detection in one Slovakian pig farm, which is the first report of evidence for the presence of the virus in the country. To estimate the prevalence in Hungary 211 oral fluid samples were collected from 23 large-scale swine herds in a systematic way and tested by real-time quantitative RT-PCR. The presence of the virus was detected in 10 of the 23 Hungarian farms (43%) included in our study. One hundred eighty-one nasal swab samples were collected cross-sectionally from three Hungarian and one Slovakian PPIV-1-positive herd and PPIV-1 was most prevalent in 6-week-old pigs on farms located in Hungary and in the 2-week-old pigs on the Slovakian farm. Phylogenetic analysis of three Hungarian and two Slovakian PPIV-1 F-gene sequences showed high-nucleotide identity (>93%) and all belonged to Clade I, together with the other European strains. © 2024 Barbara Igriczi et al.

Prevalence estimation and optimal classification methods to account for time dependence in antibody levels

Item Type Journal Article

Author P. Bedekar

Author A.J. Kearsley

Author P.N. Patrone

Abstract Serology testing can identify past infection by quantifying the immune response of an infected individual providing important public health guidance. Individual immune responses are time-dependent, which is reflected in antibody measurements. Moreover, the probability of obtaining a particular measurement from a random sample changes due to changing prevalence (i.e., seroprevalence, or fraction of individuals exhibiting an immune response) of the disease in the population. Taking into account these personal and population-level effects, we develop a mathematical

model that suggests a natural adaptive scheme for estimating prevalence as a function of time. We then combine the estimated prevalence with optimal decision theory to develop a time-dependent probabilistic classification scheme that minimizes the error associated with classifying a value as positive (history of infection) or negative (no such history) on a given day since the start of the pandemic. We validate this analysis by using a combination of real-world and synthetic SARS-CoV-2 data and discuss the type of longitudinal studies needed to execute this scheme in real-world settings. © 2022

Prevalence Estimation and Validation of New Instruments in Psychiatric Research: An Application of Latent Class Analysis and Sensitivity Analysis

Item Type Journal Article

Author B.W. Pence

Author W.C. Miller

Author B.N. Gaynes

Abstract Prevalence and validation studies rely on imperfect reference standard (RS) diagnostic instruments that can bias prevalence and test characteristic estimates. The authors illustrate 2 methods to account for RS misclassification. Latent class analysis (LCA) combines information from multiple imperfect measures of an unmeasurable latent condition to estimate sensitivity (Se) and specificity (Sp) of each measure. With simple algebraic sensitivity analysis (SA), one uses researcher-specified RS misclassification rates to correct prevalence and test characteristic estimates and can succinctly summarize a range of scenarios with Monte Carlo simulation. The authors applied LCA to a validation study of a new substance use disorder (SUD) screener and a larger prevalence study. With a traditional validation study analysis in which an error-free RS (Structured Clinical Interview for DSM-IV Axis I Disorders [SCID]; M. H. First, R. L. Spitzer, M. Gibbon, & J. Williams, 1990) is assumed, the authors estimated the screener had 86% Se and 75% Sp. Validation study estimates from LCA were 91% Se, 81% Sp (screener), 73% Se, and 98% Sp (SCID). SA in the prevalence study suggested the prevalence of SUD was underestimated by 22% because SCID was assumed to be error-free. LCA and SA can assist investigators in relaxing the unrealistic assumption of perfect RSs in reporting prevalence and validation study results. © 2009 American Psychological Association.

Prevalence estimation of anorectal malformations using German diagnosis related groups system

Item Type Journal Article

Author E. Jenetzky

Abstract Without major registries, true prevalence of rare congenital diseases is not known. Estimations for occurrence of anorectal malformation (ARM) are based on monitoring centers and epidemiological studies. The new German economical system for payment of inpatient care (G-DRG) obligates the report of each hospitalization, including diagnoses and procedures. These codes and classifications originally developed for morbidity statistics are now misused for economical purposes. Is there an epidemiological use? We present a new method to estimate national wide prevalence rate of congenital malformations exemplarily for imperforated anus. Due to the new German DRG-system, treatment data collections of the years 2002-2005 are freely accessible. This method is applicable if a life saving surgery is mandatory for newborns and has to be ciphered by specific codes. Overall, in German hospitals 1,012 children below 1 year of age are surgically treated with a reconstructive anorectal surgery during the period of 4 years. In the same time 2,817,388 babies are born in Germany. Hence the national wide prevalence rate is about 3.6 (95% CI: 3.4-3.8) per 10,000 or 1:2,784 for all different types of anal atresia requiring surgery. Main ICD-10 diagnosis Q42 was given twice this rate, probably due to at least two hospitalizations in the newborn period. The economic data of the G-DRG system can be used to estimate yearly prevalence of some rare congenital diseases in Germany, in case of specific surgical procedures. It may be a useful supplement to smaller regional registries because of larger size. Further calculations for other epidemiological questions have to be faced. © 2007 Springer-Verlag.

Prevalence Estimation of Dementia/Alzheimer’s Disease Using Health and Retirement Study Database in the United States

Item Type Journal Article

Author A.A.T. Monfared

Author N. Hummel

Author A. Chandak

Author A. Khachatryan

Author R. Zhang

Author Q. Zhang

Abstract Background: Updated prevalence estimates along the continuum of Alzheimer’s disease (AD) can foster a more nuanced and effective approach to managing AD within the current healthcare landscape. Objectives: This study aims to estimate the prevalence and severity distribution of dementia/AD (including mild, moderate, and severe stages) and all-cause mild cognitive impairment (MCI) in the United States using data from the Health and Retirement Study (HRS). Design: Retrospective study. Setting: Data from the bi-annual HRS surveys involving in-depth interviews of a representative sample of Americans aged >50 years. Participants: Dementia/AD and all-cause MCI patients from the 4 most recent HRS surveys (2014, 2016, 2018 and 2020). Measurements: AD was identified based on diagnosis (self-report). Cognitive performance (modified Telephone Interview of Cognitive Status [TICS-m]) scores in the dementia/AD range were also captured; all-cause MCI was similarly identified using the TICS-m. Dementia/AD and MCI prevalence, as well as the distribution by dementia/AD stage (mild, moderate, or severe), were estimated. Sampling weights developed by HRS were applied to ensure the sample’s representativeness of the target population and unbiased estimates for population parameters. Results: Across the four HRS surveys, the total number of HRS respondents ranged from 15,000 to 21,000 (unweighted); 7,000 to 14,000 had TICS-m scores. The estimated prevalence of AD (all severity categories combined) in the 2014, 2016, 2018, and 2020 HRS surveys was 1.2%, 1.2%, 1.3% and 1.0%, respectively using the diagnosis-based approach; using the cognitive performance-based approach, 23–27% patients had

scores in the dementia/AD ranges across the 4 surveys. The estimated prevalence of all-cause MCI was consistently 23% in each survey. In the 2020 survey, the distribution of mild, moderate, and severe disease stages was 34%, 45%, and 21%, respectively, in patients self-reporting an AD diagnosis, and 55%, 40%, and 5%, respectively in all patients meeting TICS-m threshold for dementia/AD. Conclusion: The prevalence of AD diagnosis based on self-report was approximately 1% across the 4 most recent HRS surveys and may reflect the proportion of patients who have actively sought healthcare for AD. Among HRS survey respondents with cognitive scores available, over 20% were in the dementia/AD range. The distribution of disease by stage differed for self-reported AD diagnosis vs dementia/AD based on cognitive scores. Discordance in estimates of dementia/AD and stage distributions underscores a need for better understanding of clinical practice patterns in AD diagnosis, use of clinical assessment tools, and severity classification in the United States. Accurate patient identification is needed, especially early in the AD disease continuum, to allow for timely and appropriate initiation of new anti-amyloid treatments. © The Authors 2024.

Prevalence estimation of essential tremor in Hungary between 2010 and 2020 based on the National Health Insurance Fund Database

Item Type Journal Article

Author A.K. Papp

Author Á.J. Berki

Author P. Vinnai

Author A. Ajtay

Author L. Erőss

Author G. Tamás

Abstract The published prevalence of essential tremor is variable worldwide and lacking in Central Europe. We aimed to estimate its prevalence in Hungary and to explore the locally applied therapeutic approaches. We collected data from the National Health Insurance Fund database and pharmacy database registered between 2010 and 2020. Matching the specified codes of the International Classification of Diseases and the individually tailored combination of interventions, we attempted to exclude Parkinson's disease and other tremor evoking conditions. We estimated the period prevalence of essential tremor age standardized to the European Standard Population at 378–388/100,000. After excluding patients with possible Parkinsonian syndromes, we found that 36.4% of patients with tremor did not take any medication during the study period. Most of the rest used alprazolam followed by propranolol for the longest period of time; the alprazolam and propranolol combination was the most preferred. Deep brain stimulation and ablative surgery were chosen for less than 0.5% of the patients. Our strict methods probably underestimate the essential tremor prevalence in Hungary, which, however, does not differ considerably from international results. Given the limitations of medication therapy, expanding and improving neurosurgical interventions may help improve the quality of life of patients with essential tremor. © The Author(s) 2025.

Prevalence Estimation of Protected Health Information in Swedish Clinical Text

Item Type Journal Article**Author** A. Henriksson**Author** M. Kvist**Author** H. Dalianis**Editor** Randell R.**Editor** Cornet R.**Editor** Scott P.J.**Editor** Cornet R.**Editor** Peek N.**Editor** McCowan C.

Abstract Obscuring protected health information (PHI) in the clinical text of health records facilitates the secondary use of healthcare data in a privacy-preserving manner. Although automatic de-identification of clinical text using machine learning holds much promise, little is known about the relative prevalence of PHI in different types of clinical text and whether there is a need for domain adaptation when learning predictive models from one particular domain and applying it to another. In this study, we address these questions by training a predictive model and using it to estimate the prevalence of PHI in clinical text written (1) in different clinical specialties, (2) in different types of notes (i.e., under different headings), and (3) by persons in different professional roles. It is demonstrated that the overall PHI density is 1.57%; however, substantial differences exist across domains. © 2017 European Federation for Medical Informatics (EFMI) and IOS Press.

Prevalence of attention-deficit hyperactivity disorder (ADHD): Systematic review and meta-analysis

Item Type Journal Article

Author S. Popit

Author K. Serod

Author I. Locatelli

Author M. Stuhec

Abstract Background The estimates of attention-deficit hyperactivity disorder (ADHD) prevalence across various studies are significantly variable, contributing to uncertainty in ADHD prevalence estimation. Previous systematic reviews and meta-analyses have attributed this variability primarily to the methodological characteristics of the studies, including the diagnostic criteria, source of information, and impairment requirement for the diagnosis. Methods Review identified studies reporting ADHD prevalence in representative samples of children and adults in Europe and worldwide. Studies that were conducted in the general population were included. We focused on studies that report ADHD prevalence based on clinical diagnosis (clinical diagnostic criteria based on the Diagnostic and Statistical Manual

of Mental Disorders and International Classification of Diseases criteria, other diagnostic tools, such as various scales or interviews based on clinical diagnostic criteria). PubMed/Medline was searched to identify relevant articles published until 2024/2/01. The study was registered in PROSPERO (CRD42020200220) and followed Preferred Reporting Items for Systematic Reviews and Meta-Analyses 2020 guidelines for systematic review and meta-analysis. Results In total, 117 studies were subjected to full evaluation. In the meta-analysis, 103 studies representing 159 independent datapoints were included. The overall prevalence of ADHD in register studies was 1.6%, 95% CI [0.9; 3.0], in survey studies 5.0%, 95% CI [2.9; 8.6], in one-stage clinical studies 4.2%, 95% CI [2.9; 6.0], and in two-stage clinical studies 4.8%, 95% CI [4.0; 5.8]. Conclusions Exact comparisons among studies with different diagnostic criteria and types of sampling can impact prevalence estimates. When comparing data from methodologically different studies, these factors need to be considered. © The Author(s), 2024. Prevalence of cerebral palsy in Quebec: Alternative approaches

Item Type Journal Article**Author** M. Oskoui**Author** L. Joseph**Author** L. Dagenais**Author** M. Shevell

Abstract Aim: To provide an estimate of the period prevalence of cerebral palsy (CP) in the province of Quebec. Methods: Children with CP were identified from three consecutive birth cohorts (1999-2001) from the Quebec CP Registry, covering 6 of the 17 administrative health regions of the province. Two inferential approaches were applied for period prevalence estimation, frequentist and bayesian. Results: 228 children were identified with CP. Using a frequentist approach, the overall prevalence of CP was 1.84 per 1,000 children aged 9-11 years living in those areas in 2010 (95% CI 1.60-2.08). Using a bayesian approach taking into account the uncertainty about the registry's sensitivity in capturing all cases, the overall prevalence is higher at 2.30 per 1,000 children with a 95% CI (1.99-2.65). Conclusion: Using a bayesian approach to adjust for the registry's known high specificity and lower sensitivity, the prevalence estimate is in concordance with worldwide estimates and estimates using administrative databases in western Canadian provinces. Future studies are needed to validate the diagnosis of CP within administrative databases and to evaluate possible regional trends across Canada in both prevalence and health service utilization, which may highlight disparities in healthcare delivery. Prevalence of financial fraud and scams among older adults in the United States: A systematic review and meta-analysis

Item Type Journal Article

Author D. Burnes

Author C.R. Henderson

Author C. Sheppard

Author R. Zhao

Author K. Pillemer

Author M.S. Lachs

Abstract Background. The financial exploitation of older adults was recently recognized by the Centers for Disease Control and Prevention as a serious public health problem. Knowledge of the prevalence of elder financial exploitation is mostly limited to the category of financial abuse, which occurs in relationships involving an expectation of trust. Little is known about the other major category of elder financial exploitation-elder financial fraud and scams, which is perpetrated by strangers. A valid estimate of elder financial fraud-scam prevalence is necessary as a foundation for research and prevention efforts. Objectives. To estimate the prevalence of elder financial fraud-scam victimization in the United States based on a systematic review and meta-analysis. Search Methods. Multiple investigators independently screened titles and abstracts and reviewed relevant full-text records from PubMed, Medline, PsycINFO, Criminal Justice Abstracts, Social Work Abstracts, and AgeLine databases. Selection Criteria. To maximize the validity and generalizability of prevalence estimation, we restricted eligibility to general populationbased studies (English speaking, 1990 onward) using state- or national-level probability sampling and collecting data directly from older adults. Data Collection and Analysis. Information on elder financial fraud-scam prevalence and study-level characteristics was extracted independently by 2 investigators. Meta-analysis of elder financial fraud-scam prevalence used generalized mixed models with individual studies as levels of a random classification factor. Main Results. We included 12 studies involving a total of 41 711 individuals in the meta-analysis. Overall pooled elder financial fraud-scam prevalence (up to 5-year period) across studies was 5.6% (95% confidence interval [CI] = 4.0%, 7.8%), with a 1-year period prevalence of 5.4% (95% CI = 3.2%, 7.6%). Studies using a series of questions describing specific fraud-scam events to measure victimization found a significantly higher prevalence (7.1%; 95% CI = 4.8%, 9.4%) than studies using a single, generalquestion self-report assessment approach (3.6%; 95% CI = 1.8%, 5.4%). Author's Conclusions. Elder financial fraud and scams is a common problem, affecting approximately 1 of every 18 cognitively intact, community-dwelling older adults each year; it requires further attention from researchers, clinicians, and policymakers. Elder financial fraud-scam prevalence findings in this study likely underestimate the true population prevalence. We provide methodological recommendations to limit older adult participation and reporting bias

in future population-based research. Public Health Implications. Elder financial exploitation victimization is associated with mortality, hospitalization, and poor physical and mental health. Health care professionals working with older adults likely routinely encounter patients who are fraud-scam victims. Validation of instruments to screen for elder financial fraud and scams in clinical settings is an important area of future research. Without effective primary prevention strategies, the absolute scope of this problem will escalate with the growing population of older adults.

Prevalence of mixed mania using 3 definitions

Item Type Journal Article

Author E. Vieta

Author C. Morralla

Abstract Objectives: Mixed episodes are a combination of depressive and manic symptoms in bipolar disorder (BD). We want to identify the proportion of patients who have depressive symptoms during an acute episode and also the validity of current methods for its diagnosis. Material and method: Cross-sectional multicentre study of patients with type I BD who are admitted to specialized units. 368 patients in 76 centres were included. The patients should have a well established diagnosis of BD and need

hospitalisation. The severity of the disorder and clinical status were evaluated upon admission and discharge using CGI-BP-M clinical impression scales, the Hamilton depression scale (HAMD-17) and the Young mania rating scale (YMRS). Upon admission, the necessary criteria for diagnosing a mixed type episode were recorded according to DSM-IV-TR, ICD-10 and McElroy criteria. Clinical judgment of the current type of episode was also recorded. Results: Prevalence estimations for mixed episodes were: 12.9% according to DSM-IV-TR (n = 45), 9% according to ICD-10 (n = 31), 16.7% according to McElroy criteria (n = 58), and 23.2% according to clinical judgment (n = 81). Statistically significant differences were found between the estimated prevalence rates (Cochrane's Q-test, $p < 0.0001$), with the maximum concordance level found between the McElroy and ICD-10 (Kappa = 0.66, 95% CI, 0.54-0.77). The DSM-IV-TR criteria only present moderate concordance with ICD-10 (Kappa = 0.65, 95% CI, 0.52 to 0.78) and McElroy criteria (Kappa = 0.62, 95% CI, 0.50 to 0.74). Conclusions: The definition of mixed episodes for BD must be revised to improve consensus and, consequently, therapeutic management. Current diagnostic systems, based on DSM-IV and IDC-10, only capture a limited proportion of patients suffering from mixed episodes, giving rise to important limitations concerning the therapeutic management of BP patients. © 2010 Elsevier B.V. Prevalence-Insensitive Evaluation of Diagnostic Systems Under Class Imbalance: The Harmonic Mean of Per-Class Sensitivity

Item Type Journal Article

Author J.S. Aguilar-Ruiz

Abstract In safety-critical diagnosis under class imbalance, widely used global metrics—e.g., accuracy, F-score, and MCC—conflate class-conditional behavior with class priors, often yielding overly optimistic assessments of overall performance, thereby hindering stable comparisons across datasets. We formalize the prevalence sensitivity of these indices and advance a prevalence-insensitive evaluation built solely from class-conditional rates (binary TPR/TNR; multiclass per-class sensitivities). We analyze the arithmetic, geometric, and harmonic means as class-symmetric aggregators and provide a geometric characterization of their isocurves. Empirically, on 18 UCI datasets, accuracy exceeded the harmonic mean by $\sim 3\%$ on average, but the gap widened on skewed sets (e.g., cardiocography: (Formula presented.) vs. (Formula presented.), (Formula presented.)). On a 6756-sample, 35-class tumor dataset, high overall agreement ((Formula presented.), Cohen's (Formula presented.)) coexisted with dispersed per-class sensitivities ((Formula presented.), (Formula presented.), (Formula presented.)) and moderate MCP ((Formula presented.)), evidencing weak minority-class performance despite strong accuracy. These results show that reliance on accuracy or (Formula presented.) can overstate performance precisely where it matters most, inflating perceived safety and obscuring rare-class failure modes. Prevalence-insensitive, class-symmetric means—especially the harmonic mean of per-class sensitivity—yield conservative, comparable summaries better aligned with risk-aware evaluation and deployment in critical systems. © 2025 by the author.

Author D.J. Dabbs

Abstract There is dearth of studies that provide a practical working formulation of breast cancer gene expression analysis for the surgical pathologist. ER, PR, HER2 were used, as surrogate markers to classify 205 breast carcinomas into molecular classes. Ki-67 labeling index was calculated using an image analysis system. The data was analyzed for molecular class prevalence, and inter-relationships amongst morphologic parameters, Ki-67 index, and molecular classes. Of the 205 tumors, 113 (55%) were classified as luminal A (strong ER+, HER2 negative), 34 (17%) as luminal B (weak to moderate ER+, HER2 negative), 32 (15%) as triple negative (negative for ER/PR and HER2), 8 (4%) as ERBB2 (negative for ER/PR but HER2+), 10 (5%) as luminal A-HER2 hybrid (strong ER+ and HER2+), and 8 (4%) as luminal B-HER2 hybrid (weak to moderate ER+ and HER2+). The average Ki-67 index was lowest in luminal A (15.8%), intermediate for ERBB2 (27.8%) and highest for triple negative tumors (>50%). Multivariate logistic regression analyses found the following associations: ERBB2 tumors with apocrine differentiation ($p=0.0031$); Triple negative tumors with high Ki-67 index ($p<0.0001$) and CK5 positivity ($p<0.0001$); HER2 negative-low receptor positive tumors (luminal B) with increased lymph node involvement ($p=0.0141$). The immunohistologic criteria were validated on a different set of 359 cases treated with neoadjuvant chemotherapy, which showed a pathologic complete response predominantly in ERBB2 and triple negative tumors. Immunohistochemistry is a reliable surrogate tool to classify breast carcinoma according to the gene expression profile classification.

Abstract Stroke rehabilitation seeks to accelerate motor recovery by training functional activities, but may have minimal impact because of insufficient training doses. In animals, training hundreds of functional motions in the first weeks after stroke can substantially boost upper extremity recovery. The optimal quantity of functional motions to boost recovery in humans is currently unknown, however, because no practical tools exist to measure them during rehabilitation training. Here, we present PrimSeq, a pipeline to classify and count functional motions trained in stroke rehabilitation. Our approach integrates wearable sensors to capture upper-body motion, a deep learning model to predict motion sequences, and an algorithm to tally motions. The trained model accurately decomposes rehabilitation activities into elemental functional motions, outperforming competitive machine learning methods. PrimSeq furthermore quantifies these motions at a fraction of the time and labor costs

of human experts. We demonstrate the capabilities of PrimSeq in previously unseen stroke patients with a range of upper extremity motor impairment. We expect that our methodological advances will support the rigorous measurement required for quantitative dosing trials in stroke rehabilitation. © 2022 Parnandi et al. Principled efficient triple-weighting for AUC-oriented imbalanced covariate shift

Item Type Journal Article

Author Y. Zhang

Author X. Zheng

Author T. Guo

Author D. Zhang

Author G. Wu

Author Y. Yin

Abstract Unlike traditional machine learning tasks under the independent and identically distributed (i.i.d.) assumption, Covariate Shift (CS) tackles the learning problem where training and test (instance) marginal distributions differ while conditional distributions are the same. Further, datasets (or distributions) are often class-imbalanced in practice, where AUC is a widely adopted imbalance-aware evaluation metric. However, few works have investigated the problem of AUC-targeted

imbalanced CS learning. In this work, we first provide a theoretical analysis of the ultimate learning goal, revealing key influencing factors. Inspired by the theoretical insights, we propose a new efficient triple-weighting method with univariate surrogate losses. Specifically, the proposed objective jointly incorporates three complementary weighting factors: the instance-level density ratio for correcting covariate shift, the class-wise average density ratios for aligning positive and negative sample contributions under the test distribution, and the imbalance-aware degree for alleviating class-prior bias. This design enables the model to optimize an AUC-oriented objective under the target distribution while avoiding the high computational cost of pairwise AUC losses. The proposed framework can be naturally instantiated with density-ratio-based covariate shift methods, such as static importance weighting and dynamic importance weighting. Theoretically, we provide favorable consistency and generalization guarantees. Finally, experimental results illustrate its effectiveness and robustness compared with related baselines. © 2026 Elsevier Ltd. Prior Shift Using the Ratio Estimator

Item Type Conference Paper

Author A. Vaz

Author R. Izbicki

Author R.B. Stern
Editor Louzada F.
Editor Stern J.

Editor Polpo A.
Editor Izbicki R.

Abstract Several machine learning applications use classifiers as a way of quantifying the prevalence of positive class labels in a target dataset, a task named quantification. For instance, a naive way of determining what proportion of people like a given product with no labeled reviews is to (i) train a classifier based on the Google Shopping reviews to predict whether a user likes a product given its review, and then (ii) apply this classifier to Facebook/Google+ posts about that product. It is well known that such a two-step approach, named Classify and Count, fails because of dataset shift, and thus, several improvements have been recently proposed under an assumption named prior shift. Unfortunately, these methods only explore the relationship between the covariates and the response via classifiers. Moreover, the literature lacks in the theoretical foundation to improve these techniques. We propose a new family of estimators named Ratio Estimator which is able to explore the relationship between the covariates and the response using any function $g: X \rightarrow \mathbb{R}$ and not only classifiers. We show that for some choices of g , our estimator matches standard estimators used in the literature. We also explore alternative ways of constructing functions g that lead to estimators with good performance, and compare them using real datasets. Finally, we provide a theoretical analysis of the method. © 2018, Springer International Publishing AG, part of Springer Nature.

Prioritizing conservation areas based on contributions to rarity and beta diversity in Mediterranean forest ecosystems in Türkiye

Item Type Journal Article

Author K. Özkan

Author Ö. Şentürk

Author M. Arslan

Author M.G. Negiz

Abstract The depletion of forest biodiversity arising from insufficient conservation of resources due to wood extraction, overgrazing, fire, and land use presents a significant challenge in the Mediterranean region. It becomes crucial to identify priority conservation areas for safeguarding biodiversity. We used plant species data taken from 800 plots in the Kuyucak mountain district, a typical Mediterranean forest ecosystem in Türkiye and maps of seven potential environmental predictors: elevation, aspect, slope, head index, topographical position index, landform characteristics, and bedrock geology. To assign priority areas for the conservation, local contribution to beta diversity (LCBD) and relative contribution to total rarity (RIRR) were examined with community metrics and environmental predictors, respectively. Correlation results showed that LCBD was positively related to rare species richness but negatively related to common species richness. RIRR was significantly associated with all the community metrics. According to the results of Random Forest regression models, elevation was the most important variable of LCBD, followed by slope, heat index, and pebblestone. For RIRR, the most contributed variables were elevation, heat index, limestone, and slope, respectively. The LCBD and RIRR Random Forest regression models were extrapolated along the Kuyucak mountain district, resulting in the creation of potential distribution maps for both LCBD and RIRR. Subsequently, from these maps, two distinct conservation value maps have been developed for the Kuyucak mountain district based on four conservation priority classes (Priority Class 1, Priority Class 2, Priority Class 3, and Priority Class 4): one employing a conservation cost approach and the other applying an ecology-centered approach. The results suggest that areas with elevated values of both LCBD and RIRR values are primarily situated below 1100 m on steep valley slopes, characterized by the presence of karstic limestone and intricate terrain. Compared to other areas, prioritizing the protection of such areas can provide greater benefits in contributing to ecological uniqueness. © 2024, Editura Silvica. All rights reserved.

Abstract Unit testing plays a crucial role in object-oriented software quality assurance. Unfortunately, software testing is often conducted under severe pressure due to limited resources and tight time constraints. Therefore, testing efforts have to be focused, particularly on critical classes. As a consequence, testers do not usually cover all software classes. Prioritizing unit testing effort is a crucial task. We previously investigated a unit testing prioritization approach based on software information histories. We analyzed different attributes of ten open-source Java software systems tested using the JUnit framework. We used machine learning classifiers (Multivariate Logistic Regression and Naïve Bayes) to obtain, for each system, a set of classes to be tested. The obtained sets of candidate classes have been compared to the sets of classes for which JUnit test cases have been actually developed by testers. The cross system validation (CSV) technique results showed, among others, that the sets of candidate classes suggested by machine learning classifiers properly reflect the testers' selection. In this paper, we extend

our previous work by investigating more classifiers and using leave one system out validation (LOSOV) technique. This LOSOV technique uses a combination of training datasets from different systems. The obtained results indicate that: (1) the new classifiers correctly suggest classes to be tested, and (2) tested classes are particularly well predicted in the case of large-size systems. © 2018 Universitat zu Koln. PRIS kidult anti-SPAM solution at the TREC 2005 spam track: Improving the performance of naive bayes for spam detection

Item Type Conference Paper

Author Y. Zhen

Author X. Weiran

Author C. Bo

Author H. Jiani

Author G. Jun

Abstract Recently, the spam already constituted a serious problem for both e-mail users and Internet Service Providers (ISP). Solutions to the abuse of spam would be both technical and legal regulatory. This paper reports our solution for the TREC 2005 spam track, in which we consider the use of Naive Bayes spam filter for its desirable properties (simplicity, low time and memory requirements, etc.). Then the approaches to modify the Naive Bayes by simply introducing weight and classifier assemble based on dynamic threshold are proposed, which can help to improve the accuracy of a Naive Bayes spam classifier dramatically. Additionally, we discuss some steps that must be adopted naturally thought before, such as stop list, word stemming, feature selection, class prior probabilities. The theory analysis implies these steps are not necessarily the best way to extend the Bayesian classifier, and these were also verified empirically. Many of these techniques appear to be counterintuitive but can be explained by the statistical properties of e-mail itself. Experiment results of TREC 2005 spam track demonstrate the effectiveness of the proposed method.

Author G. Pau

Editor Jiang X.

Editor Fujita H.

Abstract Visual analytics has been in the limelight as a powerful tool to support large scale management of places, people, and activities. Harnessing the power of machine learning is possible to quickly identify critical issues across thousands of cameras. Several stakeholders have voiced concerns about privacy. Visual analytics techniques can be used in facial recognition thus enabling fine-grain user tracking. This paper addresses such privacy concerns for some specific scenarios. It explores the feasibility of visual analytics in using low-cost/low-resolution thermal cameras thus delivering context-awareness information yet protecting user's privacy. This paper proposes a model able to classify and count humans, in indoor hallway settings, using low-resolution thermal pictures. The model is designed to work with YOLOv3 and leverages the power of deep-learning. Results show that it is possible to classify and count humans with over 90% accuracy based on the images from a low-cost 80x60 pixel thermal camera. The results were evaluated against the ground truth checked by a human agent and recorded through a regular camera. The study exposed possibilities and limits offered by low-cost thermal cameras and identifies the potential application scenarios. The dataset including both real and thermal images used for the training and the testing will be made available to the scientific community. © 2020 SPIE.

Privacy risk assessment method incorporating sensitivity and correlation with empirical study

Item Type Journal Article

Author R. Geng

Author T. Zhang

Author S. Li

Author Y. Xu

Abstract Introduction. User-generated content (UGC) has emerged as a prominent vector for privacy breaches, especially due to the context-dependence of data sensitivity and vulnerabilities introduced by data correlations. These challenges highlight the growing limitations of traditional assessment method s. Method. This study proposes a privacy risk quantification method integrating both attribute sensitivity and inter-attribute association, with an experimental validation conducted on the ‘Friend Identification ’ section of the <https://muchong.com> . A BERT-BiLSTM-CRF deep learning model is utilized for the automatic identification of attributes from unstructured text. Using a predefined privacy data lexicon, attribute sensitivity is quantified, and pointwise mutual information (PMI) is introduced to measure attribute associations. Combined with a privacy subject identification factor, these elements collectively quantify privacy ris k values, followed by risk level classification. Results. Ablation experiments and manual validation have confirmed the feasibility of the proposed scheme, demonstrating its capability to identify, assess, and classify privacy risks in unstructured textual data with broad applicability. Conclusion. The study validates the proposed solution theoretically, technically, and empirically, overcoming the limitations of traditional isolated-field evaluation paradigms. The method can be extended to high-sensitivity domains such as healthcare and finance, providing a basis for dynamic, risk-informed classification policies. © 2026, University of Boras. Probabilistic Contrastive Test-Time Adaptation

Item Type	Conference Paper
Author	L. You
Author	J. Lu
Author	X. Huang
Abstract	Test-time adaptation (TTA) enhances generalization against out-of-distribution data during inference. Recent advances in TTA leverage some techniques such as contrastive learning and entropy minimization to improve the discriminability and robustness of models in target domains. However, existing methods often overlook simultaneous distribution shifts of sample and label, such as long-tail distributions, and contrastive learning approaches may require substantial storage for sample pairs. In this paper, we propose a novel Probabilistic Contrastive Test-time Adaptation (PCTA) method based on Expectation Maximization (EM), which is used to estimate the von Mises Fisher (vMF) distribution of test samples to capture both sample distribution and class proportions. The estimated distributions are used for probabilistic contrastive learning to adapt feature representations and optimize classification through class-weighted entropy minimization. Experimental results show that PCTA significantly enhances the performance across various distribution shifts and outperforms state-of-the-art methods in different scenarios involving both sample and label shifts. Probabilistic deep learning regression framework for post-hazard hurricane wind damage assessment of buildings

Item Type Journal Article

Author A.A. Ewis

Author O. Nofal

Abstract Hurricanes significantly affect coastal communities, causing substantial disruption to their socio-economic systems. Therefore, post-hurricane rapid assessment is essential for effective disaster response and recovery. Traditional human-based assessments through field reconnaissance are time-consuming, leading to delays in critical decision-making. Therefore, machine learning and deep learning have emerged as powerful alternatives enabling automated, near-real-time damage evaluation. By leveraging data from past expert-classified and systematically organized events, new models can predict damage either immediately after or even during a hurricane event. This study introduces a probabilistic deep learning regression framework that predicts component-level building damage percentages using multi-view geo-coded post-disaster imagery. Unlike conventional classification models, the proposed approach estimates continuous damage ratios for eight key envelope components, enabling more detailed and loss-relevant characterization of structural damage. A pretrained convolutional backbone is integrated with a regression head to fuse features extracted from multiple building views, while a systematic hyperparameter sensitivity analysis is performed to optimize model performance. To enhance the reliability of the developed model, uncertainty quantification was incorporated using Monte Carlo dropout and bootstrapping techniques, producing confidence intervals for each prediction. Post-disaster images from Hurricane Harvey (2017), covering 436 buildings, were used as a case study to build this model. Results demonstrate that the distribution of training data strongly influences prediction accuracy across components. Both uncertainty quantification methods performed well in capturing

mean values, though they diverged in their confidence intervals. Bootstrapping offered superior uncertainty characterization, albeit with a higher computational cost compared to the Monte Carlo approach. © 2026 Elsevier Ltd.

Probabilistic facies discrimination from simultaneous seismic-inversion results in clastic reservoirs in southwestern Venezuela

Item Type Journal Article

Author J. Reverón

Author J. Roomer

Abstract Facies volumes were obtained in southwestern Venezuela reservoirs integrating rock-physics analysis and seismic-inversion results. Facies volumes showed a sandstone-shale spatial distribution that matches log data and the conceptual sedimentologic model of the reservoir. After seismic-gather conditioning, applying a simple but robust processing sequence, the signal-to-noise ratio was increased. Two angle stacks were generated to perform a simultaneous seismic inversion to obtain P-and S-wave impedance volumes. Parallel to the inversion process, rock-physics analysis was done

using rock-physics templates (RPT) for constant-cement models (CCM) to discriminate between sandstone and shale. P-and S-wave impedance bivariate probabilistic density functions (PDF) were computed from well-log data as an a priori probability. Finally, these PDFs were used to classify facies from P-and S-wave impedance volumes obtained from simultaneous inversion, using a Bayesian probabilistic approach. This classification produced two facies volumes, sandstone and shale, which honored the well information and rock-physics models. © 2014 © 2014 by The Society of Exploration Geophysicists.

Probabilistic inversion of Rayleigh-wave dispersion data: An application to Mt. Etna, Italy

Item Type Journal Article

Author L. Cauchie

Author G. Saccorotti

Abstract We present a methodology for determining the elastic properties of the shallow crust from inversion of surface wave dispersion characteristics through a fully nonlinear procedure. Using volcanic tremor data recorded by a small-aperture seismic array on Mount Etna, we measured the surface waves dispersion curves with the multiple signal classification technique. The large number of measurements allows the determination of an a priori probability density function without the need of making any assumption about the uncertainties on the observations. Using this information, we successively conducted the inversion of phase velocities using a probabilistic approach. Using a wave-number integration method, we calculated the predicted dispersion function for thousands of 1-D models through a systematic grid search investigation of shear-wave velocities in individual layers. We joined this set of theoretical dispersion curves to the experimental probability density function (PDF), thus obtaining the desired structural model in terms of an a posteriori PDF of model parameters. This process allowed the representation of the objective function, showing the non-uniqueness of the solutions and providing a quantitative view of the uncertainties associated with the estimation of each parameter. We then compared the solution with the surface wave group velocities derived from diffuse noise Green's functions calculated at pairs of widely spaced (~5-10 km) stations. In their gross features, results from the two different approaches are comparable, and are in turn consistent with the models presented in several earlier studies. © 2012 Springer Science+Business Media B.V.

Probing Ink Evaporation-Deposition Behavior for Scalable Catalyst-Layer Fabrication in PEM Electrolysis: Systematic Droplet Metrology Coupled with Explainable Machine Learning

Item Type Journal Article

Author Z. Huang

Author X. Fu

Author R. Qi

Abstract Nonuniform catalyst-ink deposition during droplet drying, such as coffee-ring formation, remains a key bottleneck for scalable fabrication of proton exchange membrane (PEM) membrane-electrode assemblies (MEAs), as it compromises catalyst-layer uniformity, pore structure, and mass transport in PEM electrolysis. This work integrates systematic single-droplet metrology with explainable machine learning to quantify the evaporation-deposition behavior of Ir-based catalyst inks, including IrO₂ and ATO-supported formulations with PFSA ionomers. Quantitative morphology descriptors were established by combining optical microscopy with 3d-profilometry-assisted interpretation to characterize thickness nonuniformity and radial deposition distribution, including normalized variance, thickness-partitioned area fractions, and an edge-to-center grayscale ratio (ECCR). A data set spanning ionomer equivalent weight (EW = 720–1100), solid content (SC = 1–4 wt %), ionomer-to-catalyst mass ratio (I/Ir = 0.1–0.4), isopropanol volume fraction (ϕ_{IPA}), and substrate temperature (T_{sub} = 50–90 °C) was used to train a multioutput gradient-boosting decision tree model. Together with SHAP analysis, the model captures trend-level relationships between formulation/process parameters and morphology metrics (training R^2 = 0.74–0.88) and identifies $\phi_{\text{IPA}} \times \text{EW}$ and $\phi_{\text{IPA}} \times T_{\text{sub}}$ as dominant interaction terms governing ECCR and deposition-pattern transitions, whereas coverage and thick-region fractions are more sensitive to I/Ir and $\phi_{\text{IPA}} \times \text{SC}$. Based on these descriptors, an empirical deposition uniformity index (DUI) was further defined to rank relative deposition uniformity and guide process-window prediction. At EW = 1100, the model predicts a robust core evaporation window of $\phi_{\text{IPA}} = 0.568 \pm 0.013$ and $T_{\text{sub}} = 60 \pm 4.4$ °C. Under $T_{\text{sub}} = 60$ °C, a favorable formulation region is further identified in the SC–I/Ir plane, corresponding to SC = 2.56–3.34 wt % and I/Ir = 0.26–0.34. Independent validation experiments confirmed that samples within the predicted window generally exhibited more uniform deposition and more stable electrochemical responses than out-of-window controls. In contrast, varying relative humidity from 30% to 80% RH and droplet volume from 0.04 to 0.4 μL caused only limited changes in the final deposition pattern. Overall, this work presents an integrated framework that combines droplet-scale morphology quantification, explainable learning, and process-window prediction, providing practical guidance for catalyst-ink formulation and scalable PEM catalyst-layer fabrication. © 2026 American Chemical Society

Procedure for combining field measurements and machine learning to quantify impact of different track parameters on ride quality of railway tracks

Item Type Journal Article

Author A. Roghani

Author R. Pall

Author E. Toma

Abstract Ride quality in terms of vibration is a fundamental factor affecting passengers' satisfaction. Every year, passenger carriers invest significantly in various aspects of their system, including track and infrastructure, to improve ride quality. The assessment of ride quality and understanding the extent of the impact of different parameters on its magnitude is essential for railway operators to make informed decisions regarding capital expenditures. This paper presents a methodology for using machine learning techniques to find the correlation between various parameters (including train speed, weather conditions, presence of track features, and composition of the track substructure) and ride quality (quantified using measurements from accelerometers mounted on a rail car). The statistical model was developed using field measurements collected over a 50 km section of VIA Rail's track in Canada. This paper describes the collected field data, the development of the statistical model, and discusses the importance of each parameter on the accuracy of the model. © IMechE 2021.

Process security assessment: Operational space classification and process security index

Item Type Journal Article

Author H.H. Lou

Author R. Muthusamy

Author Y. Huang

Abstract Many chemical processes can be operationally risky, environmentally harmful and potentially dangerous when abnormal or destructive situations occur. This is due to the fact that chemical processes are often operated under high pressures, at high temperatures, and with fast material flows and complex manufacturing mechanisms. In the extreme, catastrophes such as explosions, toxic release and loss of life will occur unexpectedly and rapidly, particularly when a terrorist who has a sufficient technical background in chemical operations attacks a plant. To assure process security, systematic and effective process security-bearing operational strategies must be developed. This paper introduces a process operational space classification method and a process operational security index. The method and the index can be an effective quantitative tool for characterizing and analysing process security, especially when the process experiences various disturbances set by saboteurs who may be technically very knowledgeable. The efficacy of the quantification method is demonstrated by its application to an exothermic batch reactor.

Abstract Federated learning (FL) enables collaborative modelling of medical images without sharing raw data, yet the severe feature- and label-shift across hospitals compromises the performance of a single global model. Recent promptbased FL frameworks such as FedOTP mitigate this issue by splitting learnable prompts into a shared and a client-specific part, but still (i) rely on entropy-regularised unbalanced optimal transport (UOT) that oversmooths tiny lesions, and (ii) inherit CLIP's location-invariant self-attention, which blurs pathological details. To overcome these limitations we introduce ProFiMed, a communication-efficient framework that combines pruned UOT with a Residual Correlative Self-Attention (RCSA) block. Pruned UOT clips the OT cost matrix and reformulates the transport as a KL projection, yielding noise-resilient vision-text alignment at $O(V)$ complexity. RCSA fuses cross-layer cross-correlation attention with correlative self-attention, re-injecting position sensitivity into the final Transformer block without updating any backbone weights. Under a 16-shot protocol on five public medical benchmarks (CT, MRI, histology and dermoscopy) our method surpasses the state-of-the-art FedOTP backbone by 5.67 pp on average and outperforms six strong plug-in variants, while keeping the same privacy and communication budget. Extensive ablations reveal that pUOT and RCSA are complementary, robust to threshold and hyper-parameter choices, and scalable to heterogeneous hospital distributions. © 2025 IEEE.

Author J. Rudi

Abstract We evaluated quantitative measurement series (MS) with 18F-FDG and PET and compared different quantification methods for prediction of individual survival in patients with metastatic colorectal cancer receiving chemotherapy with 5-fluorouracil, folinic acid, and oxaliplatin (FOLFOX). Methods: The study comprised 25 patients. All patients were examined before the onset of FOLFOX therapy and after completion of the first and fourth cycles. SUV, fractal dimension (FD), a 2-compartment model with computation of k_1 , k_2 , k_3 , and k_4 , and vascular fraction

(VB) were used for data evaluation. Survival data served as a reference for the PET data. Discriminant analysis (DA), regression, and best-subset analysis were applied to the data. Results: Twenty of 25 patients died up to 801 d after the first PET study. A cutoff of 1 y (364 d) was used to classify the patients into 2 a priori groups, namely the short- and long-term survival groups. DA was used to predict the 2 categories using SUV and kinetic parameters of 18F-FDG metabolism as predictor variables. SUV provided a correct classification rate (CCR) ranging from 62% to 69%. SUV of the third MS resulted in a CCR of 69% as a single parameter. The best results were yielded by the use of kinetic parameters (k_1 , k_3 , VB, and FD) as predictor variables. CCR was 78% using kinetic 18F-FDG parameters of the first and third MS, in comparison with 69% for the corresponding SUVs. A multiple linear regression model was applied to the data to assess the relationship between individual survival and the PET data. The best-subset method revealed a correlation coefficient of 0.850 for the kinetic parameters of the first (k_3 , k_4 , VB, and FD) and third (k_1 , k_2 , k_4 , and VB) MS. Conclusion: The combination of kinetic parameters of the first and the third MS is acceptable for classification into a short or long survival class. Furthermore, even an individual prognosis of survival can be achieved using kinetic 18F-FDG parameters of the first and third MS.

Prognostic Power of Quantitative Assessment of Functional Mitral Regurgitation and Myocardial Scar Quantification by Cardiac Magnetic Resonance

Item Type Journal Article**Author** T.K.M. Wang**Author** D. Kocyigit**Author** H. Choi**Author** C.M. Anthony**Author** N. Chan**Author** J. Bullen**Author** Z.B. Popović**Author** S.R. Kapadia**Author** A. Krishnaswamy**Author** B.P. Griffin**Author** S.D. Flamm**Author** W.H.W. Tang**Author** D.H. Kwon

Abstract **BACKGROUND:** The severity classification of functional mitral regurgitation (FMR) remains controversial despite adverse prognosis and rapidly evolving interventions. Furthermore, it is unclear if quantitative assessment with cardiac magnetic resonance can provide incremental risk stratification for patients with ischemic cardiomyopathy (ICM) or non-ICM (NICM) in terms of FMR and late gadolinium enhancement (LGE). We evaluated the impact of quantitative cardiac magnetic resonance parameters on event-free survival separately for ICM and NICM, to assess prognostic FMR thresholds and interactions with LGE quantification. **METHODS:** Patients (n=1414) undergoing cardiac magnetic resonance for cardiomyopathy (ejection fraction<50%) assessment from April 1, 2001 to December 31, 2017 were evaluated. The primary end point was all-cause death, heart transplant, or left ventricular assist device implantation during follow-up. Multivariable Cox analyses were conducted to determine the impact of FMR, LGE, and their interactions with event-free survival. **RESULTS:** There were 510 primary end points, 395/782 (50.5%) in ICM and 114/632 (18.0%) in NICM. Mitral regurgitation-fraction per 5% increase was independently associated with the primary end point, hazards ratios (95% CIs) of 1.04 (1.01-1.07; P=0.034) in ICM and 1.09 (1.02-1.16; P=0.011) in NICM. Optimal mitral regurgitation-fraction threshold for moderate and severe FMR were $\geq 20\%$ and $\geq 35\%$, respectively, in both ICM and NICM, based on the prediction of the primary outcome. Similarly, optimal LGE thresholds were $\geq 5\%$ in ICM and $\geq 2\%$ in NICM. Mitral regurgitation-fraction $\times$ LGE emerged as a significant

interaction for the primary end point in ICM ($P=0.006$), but not in NICM ($P=0.971$).
CONCLUSIONS: Mitral regurgitation-fraction and LGE are key quantitative cardiac magnetic resonance biomarkers with differential associations with adverse outcomes in ICM and NICM. Optimal prognostic thresholds may provide important clinical risk prognostication and may further facilitate the ability to derive selection criteria to guide therapeutic decision-making. © 2023 Lippincott Williams and Wilkins. Proposal and evaluation of methods using the quantification theory and machine learning for detecting C&C server used in a botnet

Item Type Conference Paper**Author** S. Okayasu**Author** R. Sasaki**Editor** Ahamed S.I.**Editor** Chang C.K.**Editor** Chu W.**Editor** Crnkovic I.**Editor** Hsiung P.-A.**Editor** Huang G.**Editor** Yang J.

Abstract In recent years, the damage caused by botnets has increased and become a big problem. To solve this problem, we proposed a method to detect unjust C&C servers by using Hayashi's quantification theory class II. This method is able to detect unjust C&C servers, even if they are not included in a blacklist. However, it was predicted that the detection rate for this method decreases with passing time. Therefore, we have been continuing the investigation of the detection rate and adjusting the optimal detection method in different time periods. This paper deals with the results of an investigation for 2014. In addition, we newly introduce a method using a support vector machine (SVM) for comparison with quantification theory class II. We found that the detection rates by using quantification theory class II and those by the SVM are both very good, with very little difference in accuracy between them. © 2015 IEEE.

Protein spot detection and quantification in 2-DE gel images using machine-learning methods

Item Type Journal Article

Author P. Tsakanikas

Author E.S. Manolakos

Abstract Two-dimensional gel electrophoresis (2-DE) is the most established protein separation method used in expression proteomics. Despite the existence of sophisticated software tools, 2-DE gel image analysis still remains a serious bottleneck. The low accuracies of commercial software packages and the extensive manual calibration that they often require for acceptable results show that we are far from achieving the goal of a fully automated and reliable, high-throughput gel processing system. We present a novel spot detection and quantification methodology which draws heavily from unsupervised machine-learning methods. Using the proposed hierarchical machine learning-based segmentation methodology reduces both the number of faint spots missed (improves sensitivity) and the number of extraneous spots introduced (improves precision). The detection and quantification performance has been thoroughly evaluated and is shown to compare favorably (higher F-measure) to a commercially available software package (PDQuest). The whole image analysis pipeline that we have developed is fully automated and can be used for high-throughput proteomics analysis since it does not require any manual intervention for recalibration every time a new 2-DE gel image is to be analyzed. Furthermore, it can be easily parallelized for high performance and also applied without any modification to prealigned group average gels. © 2011 WILEY-VCH Verlag GmbH & Co. KGaA, Weinheim.

Protein-protein interactions classification from text via local learning with class priors

Item Type Conference Paper

Author Y. He

Author C. Lin

Abstract Text classification is essential for narrowing down the number of documents relevant to a particular topic for further pursuit, especially when searching through large biomedical databases. Protein-protein interactions are an example of such a topic with databases being devoted specifically to them. This paper proposed a semi-supervised learning algorithm via local learning with class priors (LL-CP) for biomedical text classification where unlabeled data points are classified in a vector space based on their proximity to labeled nodes. The algorithm has been evaluated on a corpus of biomedical documents to identify abstracts containing information about protein-protein interactions with promising results. Experimental results show that LL-CP outperforms the traditional semisupervised learning algorithms such as SVM and it also performs better than local learning without incorporating class priors. © 2010 Springer-Verlag Berlin Heidelberg.

Proteomic analysis of eutopic and ectopic endometriotic tissues based on isobaric peptide tags for relative and absolute quantification (iTRAQ) method

Item Type Journal Article

Author P. Marianowski

Author I. Szymusik

Author J. Malejczyk

Author M. Hibner

Author M. Wielgoś

Abstract **OBJECTIVE:** The present study aimed at performing proteomic analysis of matched eutopic endometrium and ovarian endometrioid cysts from women with endometriosis in order to discover any abnormal protein expression related to the disease. **DESIGN AND SETTING:** The study included 8 women with stage III/IV endometriosis according to revised American Fertility Society (rAFS) classification

and one woman with no signs of the disease as a reference. Proteomic analysis was performed using a novel isobaric tag-based methodology for relative and absolute peptide quantification (iTRAQ) coupled with multidimensional liquid chromatography and tandem mass spectrometry. RESULTS: The selection of 419 proteins was found in all endometriosis specimens. Using normal eutopic endometrium from woman without endometriosis as a reference, some proteins expressions were significantly increased in all endometriosis samples. They included collagen $\alpha 1$ (XIV), calmodulin, collagen α (VI), plexin, integrin $\alpha V\beta 3$, transgelin, desmin, and vimentin. The comparison of these proteins' expression in paired eutopic and ovarian endometriosis samples has revealed that only vimentin was significantly increased in ovarian endometrioma. CONCLUSIONS: It was confirmed that endometriosis is associated with different expression of proteins in endometriotic samples. Nevertheless, further studies seem to be necessary as they may reveal possible markers that would be useful in clinical diagnosis of the disease. © 2013 Neuroendocrinology Letters.

Proteomics-driven innovations in plant-based foods: Current advances, emerging technologies, and future perspectives

Item Type Journal Article

Author F. Boukid

Abstract Despite rapid market growth, plant-based foods such as meat analogs, plant-based milk, yogurt alternatives, and fermented products still fall short of matching the sensory, structural, and nutritional qualities of animal-based counterparts, primarily due to simple ingredient substitution that fails to reproduce the molecular structure, interactions, and functional properties required for optimal texture, flavor, and nutritional performance. Proteomics, using advanced mass spectrometry (MS) and label-free quantification methods, provides an approach to analyze plant protein composition, structure, interactions, and modifications, enabling targeted functional improvements. This review describes how proteomic workflows inform formulation across three areas. First, protein compositional and structural characterization employs techniques such as liquid chromatography-tandem mass spectrometry (LC-MS/MS) and differential scanning calorimetry (DSC) coupled with MS to map protein composition and structural behavior, supporting decisions on protein sources, fractionation, and purification. Second, indirect proteomic methods coupled with other non-proteomic complementary tools are used to determine structure–function relationships induced by processing to examine processing-induced crosslinking, enzymatic modifications, and lipid–protein interactions that influence texture. Third, targeted MS methods, including selected reaction monitoring (SRM) and parallel reaction monitoring (PRM), are applied to profile off-flavor compounds and identify protein modification sites relevant to sensory and nutritional properties. By integrating proteomic data with processing strategies, this review outlines how proteomics can be used to examine key functional attributes related to texture, flavor, and nutritional quality in plant-based foods. Significance: This review highlights the pivotal role of proteomics in advancing next-generation plant-based foods. Proteomic analysis enables an in-depth understanding of plant protein structure, composition, interactions, and bioactivity, providing critical insights for the development of functionally enhanced and consumer-acceptable alternatives. By integrating proteomics with AI, machine learning, multi-omics approaches, and cutting-edge analytical tools such as spatial proteomics and mass spectrometry imaging, the review demonstrates how protein functionality, flavor, texture, nutrition, and allergenicity can be optimized. Furthermore, it emphasizes the potential of proteomics to accelerate innovation in personalized nutrition, support sustainable and circular food systems, improve food safety, and reduce waste by valorizing plant-based by-products. This work serves as a roadmap for researchers and industry stakeholders seeking to leverage proteomics to design novel, high-quality, and sustainable plant-based protein products. © 2026 Elsevier B.V.

Prototype-guided cyclic federated learning with knowledge distillation

Item Type Journal Article

Author Q. Meng

Author Y. Zhao

Author X. Li

Author S. Chen

Abstract In this paper, we propose a novel federated learning (FL) framework, termed Prototype-Guided Cyclic Federated Learning with Knowledge Distillation (PCFedKD), to address the challenges of data heterogeneity in distributed machine learning. Unlike traditional FL models, PCFedKD incorporates global and local prototypes to enable personalized model training while ensuring efficient global knowledge sharing. The framework leverages a cyclic training approach, where clients sequentially engage in knowledge distillation (KD) to preserve and refine knowledge across training rounds. KD enables the efficient transfer of knowledge among clients, improves learning accuracy, and reduces communication overhead.

Additionally, the use of prototypes provides class-specific representations of data, which help align global knowledge with local client-specific data distributions. Global prototypes capture shared knowledge among clients, while local prototypes guide client-specific personalization, enabling improved model adaptation and performance. To summarize, PCFedKD establishes a lightweight and privacy-preserving FL paradigm that jointly enhances global consensus and local personalization through prototype-guided cyclic distillation. Extensive experiments demonstrate that our method significantly outperforms benchmark models, achieves higher accuracy, faster convergence, and improved scalability across diverse datasets, including those with feature and label shifts. The results highlight the practical applicability and robustness of the proposed framework in real-world heterogeneous FL scenarios. © 2026 Elsevier B.V.

Proximal detecting invertebrate pests on crops using a deep residual convolutional neural network trained by virtual images

Item Type Journal Article

Author H. Liu

Author J.S. Chahl

Abstract Detecting invertebrate pests on crops at early stages is essential for pest management. Traditionally, traps were used to sample pests and then human experts undertook classification and counting to estimate the levels of infestation, which is subjective,

error-prone and labour intensive. Recently, semi-automatic pest detection is possible by using computer vision technologies to classify and count pest samples in laboratories or insect traps, however, the decision made by the laboratory-based or trap-based approaches are still too late for more optimised pest management decisions. Today, precision agriculture needs detection of pests on crops so that real-time actions can be taken or optimised decision can be made based on accurate information of time and location pest occurs. In this study, we used computer vision and machine learning technologies to detect invertebrates on crops in the field. We first evaluated the performances of the state-of-art convolutional neural networks (CNNs) and proposed a standard training pipeline. Facing the challenge of rapidly developing comprehensive training data, we used a novel method to generate a virtual database which was successfully used to train a deep residual CNN with an accuracy of 97.8% in detecting four species of pests in farming environments. The proposed method can be applied to a robotic system for proximal detection of invertebrate pests on crops in real-time. © 2021 Elsevier B.V.

PSDC: A Prototype-Based Shared-Dummy Classifier Model for Open-Set Domain Adaptation

Item Type Journal Article

Author Z. Liu

Author G. Chen

Author Z. Li

Author Y. Kang

Author S. Qu

Author C. Jiang

Abstract Open-set domain adaptation (OSDA) aims to achieve knowledge transfer in the presence of both domain shift and label shift, which assumes that there exist additional unknown target classes not presented in the source domain. To solve the OSDA problem, most existing methods introduce an additional unknown class to the source classifier and represent the unknown target instances as a whole. However, it is unreasonable to treat all unknown target instances as a group since these unknown instances typically consist of distinct categories and distributions. It is challenging to identify all unknown instances with only one additional class. In addition, most existing methods directly introduce marginal distribution alignment to alleviate distribution shift between the source and target domains, failing to learn discriminative class boundaries in the target domain since they ignore categorical discriminative information in the adaptation. To address these problems, in this article, we propose a novel prototype-based shared-dummy classifier (PSDC) model for the OSDA. Specifically, our PSDC introduces an auxiliary dummy classifier to calibrate the source classifier and simultaneously develops a weighted adaptation procedure to align class-wise prototypes for adaptation. We further design a pseudo-unknown learning algorithm to reduce the open-set risk. Extensive experiments on Office-31, Office-Home, and VisDA datasets show that the proposed PSDC can outperform existing methods and achieve the new state-of-the-art performance. The code will be made public. © 2013 IEEE.

Abstract

Weakly supervised object detection (WSOD) using image-level labels has gained attention in the computer vision community. Most advanced WSOD approaches generate instance-level labels based on class activation maps (CAMs), which are limited by incomplete box labels and sparse information regarding class labels. These inaccurate pseudo-labels mislead the training of the subsequent detection module, thus hampering detection performance. To address these issues, we propose a novel pseudo-label enhancement (PLE) framework for a one-stage WSOD method that consists of a CAM reassembly (CAMR) and a composite scoring module (CSM). The CAMR explores the collaboration between class priors from CAMs and the semantic-aware grouping ability of self-supervised vision transformers (ViTs). Specifically, CAMR initially propagates object localization cues from CAMs to feature maps obtained using a self-supervised ViT. Subsequently, CAMR utilizes the patch affinity of these feature maps to extract more integral object information and improve the instance localization accuracy and completeness. Subsequently, the reassembled CAMs are refined using a multi-threshold strategy to generate bounding-box pseudo-labels. The CSM replaces one-hot labels with soft-class labels that leverage localization precision and classification confidence to counter information sparseness limitations. The proposed PLE is evaluated using the PASCAL VOC and MS-COCO datasets. The experimental results demonstrate that the performance of PLE surpasses that of the advanced methods. On average, PLE improves by 7.1% mAP on the VOC 2007 test set and 6.0% mAP on the MS-COCO 2017 validation set compared with the one-stage WSOD method. © 2025

Psychiatric Treatments with Short-Duration Psychedelics and AI-Driven Behavioral Monitoring

Item Type Journal Article

Author R.B. Kargbo

Abstract Integrating advanced pharmaceutical innovations and artificial intelligence (AI) offers transformative potential for psychiatric care. This Patent Highlight reviews novel therapeutic strategies, including the synergistic use of monoamine antidepressants and short-duration psychedelics, alongside AI-driven behavioral efficacy tracking. The combination of selective serotonin reuptake inhibitors (SSRIs) with short-acting psychedelics, such as N,N-dimethyltryptamine (DMT) and psilocybin, provides rapid and sustained improvements in treatment-resistant depression and anxiety. Meanwhile, AI-enhanced behavioral monitoring leverages motion tracking and machine learning to quantify treatment outcomes in animal models, accelerating drug development. Together, these approaches redefine therapeutic paradigms, offering personalized and effective treatments for psychiatric disorders. Published 2025 by American Chemical Society

PU-KBS: A Robust Positive and Unlabeled Learning Framework with Key Band Selection for One-Class Hyperspectral Image Classification

Item Type Journal Article

Author Z. Liu

Author H. Zhao

Author X. Wang

Author S. Wang

Author J. Li

Author Y. Zhong

Abstract Positive and unlabeled (PU) learning is aimed at building a binary classifier to distinguish the target from the background using only the known positive samples, which is an advanced solution for the hyperspectral target detection (HTD) task. However, when PU learning (PUL) meets complex hyperspectral scenarios, there are two main challenges: 1) How to estimate the class prior accurately? The class prior, i.e., the target proportion, is an important prior for PUL to learn the discriminant boundary, but it is difficult to estimate in hyperspectral imagery, due to the interclass spectral similarity and 2) How to remove redundancy and improve the discriminative features of the target? The diagnostic spectral feature extraction is important for the weakly supervised PUL models as it can help with separating the target from the background. In this article, to tackle these challenges, a robust PUL framework with key band selection (PU-KBS) is proposed, which is modeled as an end-to-end and class prior free PUL framework, where the accurate class prior and the most discriminative key band subset are jointly initialized and iteratively updated until

reaching the optimal result by evolutionary search. Meanwhile, a deep PUL detector is introduced for guiding the subsequent search direction and discriminative deep feature extraction. The proposed PU-KBS framework was verified using different hyperspectral datasets, where accurate class prior estimation, diagnostic spectral characteristics, and robust detection results could be obtained simultaneously by the PU-KBS framework. Furthermore, the improvement in band selection interpretability and detection performance was proven experimentally. © 1980-2012 IEEE.

Abstract Positive-unlabeled learning (PU learning) is an important case of binary classification where the training data only contains positive and unlabeled samples. The current state-of-the-art approach for PU learning is the cost-sensitive approach, which casts PU learning as a cost-sensitive classification problem and relies on unbiased risk estimator for correcting the bias introduced by the unlabeled samples. However, this approach requires the knowledge of class prior and is subject to the potential label noise. In this paper, we propose a novel PU learning approach dubbed PULNS, equipped with an effective negative sample selector, which is optimized by reinforcement learning. Our PULNS approach employs an effective negative sample selector as the agent responsible for selecting negative samples from the unlabeled data. While the selected, likely negative samples can be used to improve the classifier, the performance of classifier is also used as the reward to improve the selector through the REINFORCE algorithm. By alternating the updates of the selector and the classifier, the performance of both is improved. Extensive experimental studies on 7 real-world application benchmarks demonstrate that PULNS consistently outperforms the current state-of-the-art methods in PU learning, and our experimental results also confirm the effectiveness of the negative sample selector underlying PULNS. Abstract Background: The prevalence of pure stress urinary incontinence (P-SUI) and the role of urodynamic investigation (UDI) prior to surgery for stress urinary incontinence (SUI) is debated. Since the exact prevalence of P-SUI is not clear, its clinical and economic impact is not well defined. The aims of this study were to evaluate the prevalence of P-SUI in a population of women who underwent UDI for urinary incontinence (UI), also assessing: 1) the correspondence between clinical diagnosis of P-SUI and urodynamic findings; 2) the analysis of costs in terms of UDI and eventually post-UDI avoided surgical procedures. Methods: A single cohort of women who underwent UDI for UI between January 2012 and July 2016 was prospectively collected and retrospectively analyzed. Clinical P-SUI was defined by the strict criteria of the International Continence Society. For each patient, history, physical examination and UDI were collected. The correspondence between clinical and urodynamic findings of P-SUI was analyzed. The rate of clinical P-SUI changed after performing UDI and the number of unnecessary intervention after UDI were reported. A wide cost analysis of UDIs, and the amount of surgical procedures that were believed unnecessary after UDI was reported. Results: Stress urinary incontinence was present in 323/544 (59.4%) patients. The prevalence of clinical P-SUI was 20.7% (67/323), while the prevalence of complicated SUI (C-SUI) was 79.3% (256/323). After UDI, diagnosis of P-SUI decreased to 18.3% (59/232). In 10.2% of cases (6/59) the scheduled middle urethral sling (MUS) was suppressed after the UDI results because 3/6 cases had detrusor overactivity and urge incontinence, in 2/6 cases SUI was treated with a conservative management, in 1/6 case an important voiding dysfunction was detected. Considering the national reimbursement in our country, the cost of each UDI was 296.5 euros and the total amount was 17,493.5 euros. So far the surgery-related savings covered 61.7-105.0% of the costs of total number of UDIs performed in the uncomplicated patients.

Conclusions: The prevalence of clinical P-SUI is relevant, involving about 20% of women with clinical SUI. Although the correspondence between clinical and urodynamic diagnosis was high, we demonstrated that UDI may help in some cases to avoid an inappropriate surgical treatment. Therefore, UDI prior to SUI surgery should be considered to achieve a correct diagnosis and a proper therapeutic strategy. © 2019 The Author(s).

Abstract Background/Objectives: Magnetic resonance spectroscopy (MRS) is a valuable tool for studying metabolic processes in vivo. While numerous quantification methods exist, the advanced method for accurate, robust, and efficient spectral fitting (AMARES) is among the most used. This study introduces pyAMARES, an open-source Python implementation of AMARES, addressing the need for a flexible, user-friendly, and versatile MRS quantification tool within the Python ecosystem. Methods: PyAMARES was developed as a Python library, implementing the AMARES algorithm with additional features such as multiprocessing capabilities and customizable objective functions. The software was validated against established AMARES implementations (OXSA and jMRUI) using both simulated and in vivo MRS data. Monte Carlo simulations were conducted to assess robustness and accuracy across various signal-to-noise ratios and parameter perturbations. Results: PyAMARES utilizes spreadsheet-based prior knowledge and fitting parameter settings, enhancing flexibility and ease of use. It demonstrated comparable performance to existing software in terms of accuracy, precision, and computational efficiency. In addition to conventional AMARES fitting, pyAMARES supports fitting without prior knowledge, frequency-selective AMARES, and metabolite residual removal from mobile macromolecule (MM) spectra. Utilizing multiple CPU cores significantly enhances the performance of pyAMARES. Conclusions: PyAMARES offers a robust, flexible, and user-friendly solution for MRS quantification within the Python ecosystem. Its open-source nature, comprehensive documentation, and integration with popular data science tools enhance reproducibility and collaboration in MRS research. PyAMARES bridges the gap between traditional MRS fitting methods and modern machine learning frameworks, potentially accelerating advancements in metabolic studies and clinical applications. © 2024 by the authors.

QuAcc: Using Quantification to Predict Classifier Accuracy Under Prior Probability Shift

Item Type Journal Article

Author L. Volpi

Author A. Moreo

Author F. Sebastiani

Abstract Using cross-validation to predict the accuracy of a classifier on unseen data can be done reliably only in the absence of dataset shift, i.e., when the training data and the unseen data are IID. In this work we deal instead with the problem of predicting classifier accuracy on unseen data affected by prior probability shift (PPS), an important type of dataset shift. We propose QuAcc, a method built on top of “quantification” algorithms robust to PPS, i.e., algorithms devised for estimating the prevalence values of the classes in unseen data affected by PPS. QuAcc is based on the idea of viewing the cells of the contingency table (on which classifier accuracy is computed) as classes, and of estimating, via a quantification algorithm, their prevalence values on the unseen data labelled by the classifier. We perform systematic experiments in which we compare the prediction error incurred by QuAcc with that of state-of-the-art classifier accuracy prediction (CAP) methods. © The Author(s) 2025

Quadruply stochastic gradients for large scale nonlinear semi-supervised AUC optimization

Item Type Conference Paper

Author W. Shi

Author B. Gu

Author H. Huang

Editor Kraus S.

Abstract Semi-supervised learning is pervasive in real-world applications, where only a few labeled data are available and large amounts of instances remain unlabeled. Since AUC is an important model evaluation metric in classification, directly optimizing AUC in semi-supervised learning scenario has drawn much attention in the machine learning community. Recently, it has been shown that one could find an unbiased solution for the semi-supervised AUC maximization problem without knowing the class prior distribution. However, this method is hardly scalable for nonlinear classification problems with kernels. To address this problem, in this paper, we propose a novel scalable quadruply stochastic gradient algorithm (QSG-S2AUC) for nonlinear semi-supervised AUC optimization. In each iteration of the stochastic optimization process, our method randomly samples a positive instance, a negative instance, an unlabeled instance and their random features to compute the gradient and then update the model by using this quadruply stochastic gradient to approach the optimal solution. More importantly, we prove that QSGS2AUC can converge to the optimal solution in $O(1/t)$, where t is the iteration number. Extensive experimental results on a variety of benchmark datasets show that QSG-S2AUC is far more efficient than the existing state-of-the-art algorithms for semi-supervised AUC maximization, while retaining the similar generalization performance. © 2019 International Joint Conferences on Artificial Intelligence. Qualitative analysis of the hodgkin-huxley model of neuron excitability based on classification rules

Item Type Conference Paper**Author** V. Martsenyuk**Author** Y. Rudyak**Author** A. Sverstiuk**Author** Z. Mayhruk**Author** A. Horkunenko**Author** M. Kasianchuk**Editor** Fisun M.**Editor** Krainyk Y.

Abstract The proposed multivariate method of qualitative analysis of models of electrophysiological processes is an approach that allows to solve problems of classification of excitability of cells which cannot be solved by other traditional methods, for example stability theory, or boundary cycles. As a whole, the method combines the Monte Carlo approach for the formation of training kits and the data mining classification algorithms: the sequential coverage method with the generation of classification rules and the induction method of the decision tree. The advantages of the classification rules, which can be built on the 5th step of the algorithm, are that they correspond to the natural reflection of knowledge in the thinking of people and are more expressive. In addition, the sequential coverage algorithm is easier to implement and debug than the recursive algorithms of decision trees, and its computational complexity is simpler than that of finite state machines. The decision tree induction method, being more complex to implement, allows visualization and a priori probability values for the type of cell excitability based on the relationship between the initial values and the velocity parameters in the Hodgkin-Huxley model. The developed method consists of 5 stages. The approach is proven in the form of software in the Java-

class package. Copyright © 2019 for this paper by its authors.

Qualitative and quantitative analysis of chlorinated solvents using Raman spectroscopy and machine learning

Item Type Conference Paper

Author M.N. Leger

Author K. Hennessey

Author M.G. Madden

Abstract The unambiguous identification and quantification of hazardous materials is of increasing importance in many sectors such as waste disposal, pharmaceutical manufacturing, and environmental protection. One particular problem in waste disposal and chemical manufacturing is the identification of solvents into chlorinated or non-chlorinated. In this work we have used Raman spectroscopy as

the basis for a discrimination and quantification method for chlorinated solvents. Raman spectra of an extensive collection of solvent mixtures (200+) were collected using a JY-Horiba LabRam, infinity with a 488 nm excitation source. The solvent mixtures comprised of several chlorinated solvents: dichloromethane, chloroform, and 1,1,1-trichloroethane, mixed with solvents such as toluene, cyclohexane and/or acetone. The spectra were then analysed using a variety of chemometric techniques (Principal Component Analysis and Principal Component Regression) and machine learning (Neural Networks and Genetic Programming). In each case models were developed to identify the presence of chlorinated solvents in mixtures at levels of ~5%, to identify the type of chlorinated solvent and then to accurately quantify the amount of chlorinated solvent.

Abstract OBJECTIVE To establish a high-performance liquid chromatography (HPLC) fingerprint and a multi-component quantification method for Qiongyu Runfei Paste, and to construct a multidimensional quality evaluation approach by integrating chemical pattern recognition techniques, so as to provide a reference for quality control. METHODS An Agilent Eclipse Plus C18 column (4.6 mm × 250 mm, 5 μm) was used at 30 °C. The mobile phase consisted of acetonitrile (A) and 0.1% phosphoric acid aqueous solution (B) with gradient elution. The flow rate was 1.0 mL·min⁻¹, the detection wavelength was 290 nm, and the injection volume was 10 μL. The contents of six marker compounds, namely gallic acid, neochlorogenic acid, chlorogenic acid, cryptochlorogenic acid B, cryptochlorogenic acid A, and cryptochlorogenic acid C, were determined. Using the Similarity Evaluation System for Chromatographic Fingerprint of Traditional Chinese Medicine (2012), HPLC fingerprints of 10 batches of samples were established, common peaks were identified, and similarity analysis was performed. Based on the peak areas and relative peak areas of the common fingerprint peaks, hierarchical cluster analysis (HCA), principal component analysis (PCA), and partial least squares-discriminant analysis (PLS-DA) were applied to evaluate the quality of the 10 batches of Qiongyu Runfei Paste. RESULTS A total of 15 common peaks were identified in the HPLC fingerprint of Qiongyu Runfei Paste, and six components were identified as gallic acid, neochlorogenic acid, chlorogenic acid, cryptochlorogenic acid B, cryptochlorogenic acid A, and cryptochlorogenic acid C. The similarity values of the fingerprints of all 10 batches were greater than 0.97. HCA showed that the 10 batches could be clustered into two groups according to component content and proportion. PCA and PLS-DA further confirmed this classification and identified seven components, including chlorogenic acid, cryptochlorogenic acid A, and cryptochlorogenic acid C, as the main marker compounds contributing to inter-batch quality differences. CONCLUSION The established fingerprint and content determination methods showed high accuracy and good reproducibility. Combined with chemometric techniques, they can be used for holistic quality evaluation and control of Qiongyu Runfei Paste. © (2026), (Editorial Office of Chinese Journal of Hospital Pharmacy). Quantification in data streams: Initial results

Item Type Conference Paper

Author A.G. Maletzke

Author D.M. Dos Reis

Author G.E.A.P.A. Batista

Abstract In the last decades, learning from data streams has attracted the attention of researchers and practitioners due to its large number of applications. These applications have motivated the research community to propose a significant number of methods that can be used to solve problems in diverse tasks, more prominently in classification, prediction, and clustering. However, a relevant task known as quantification has remained largely unexplored. The quantification goal is to provide an estimate of the class prevalence in an unlabeled set. In this paper, we discuss the relevance and challenges of quantification for data streams and compare how it differs from the batch setting, in which quantification has attracted more attention from the research community. We propose an algorithm to estimate the class distribution in a data stream and frame our algorithm in the active learning framework. In addition, we define two other approaches as baseline and topline strategies for this problem. The experimental results demonstrate that our algorithm has significantly higher quantification accuracy than the baseline and almost as large as the topline while requiring a fraction of the true labels requested by the latter approach. © 2017 IEEE.

Quantification in social networks

Item Type Conference Paper**Author** L. Milli**Author** A. Monreale**Author** G. Rossetti**Author** D. Pedreschi**Author** F. Giannotti**Author** F. Sebastiani**Editor** Gaussier E.**Editor** Cao L.**Editor** Gallinari P.**Editor** Kwok J.**Editor** Pasi G.**Editor** Zaiane O.

Abstract In many real-world applications there is a need to monitor the distribution of a population across different classes, and to track changes in this distribution over time. As an example, an important task is to monitor the percentage of unemployed adults in a given region. When the membership of an individual in a class cannot be established deterministically, a typical solution is the classification task. However, in the above applications the final goal is not determining which class the individuals belong to, but estimating the prevalence of each class in the unlabeled data. This task is called quantification. Most of the work in the literature addressed the quantification problem considering data presented in conventional attribute format. Since the ever-growing availability of web and social media we have a flourish of network data representing a new important source of information and by using quantification network techniques we could quantify collective behavior, i.e., the number of users that are involved in certain type of activities, preferences, or behaviors. In this paper we exploit the

homophily effect observed in many social networks in order to construct a quantifier for networked data. Our experiments show the effectiveness of the proposed approaches and the comparison with the existing state-of-the-art quantification methods shows that they are more accurate. © 2015 IEEE.

Quantification Method for Assessment of Asteroid Resource Accessibility

Item Type Conference Paper

Author K.I. Alvarado

Author M.C.F. Bazzocchi

Abstract Asteroid mining and retrieval have been explored as viable alternatives to supplying resources from Earth for space missions. Various methods for determining the accessibility of near-Earth asteroids have been presented; however, this method focuses on the quantity and types of resources that are available within a certain energy constraint given a redirection time frame. Lambert's problem is solved to determine the optimal transfer orbit between the Earth and asteroid for rendezvous. A genetic algorithm is used to determine the minimum energy for transfer with varying flight durations and launch dates. The physical properties and spectral classifications of known asteroids are used to estimate the quantity and chemical composition of accessible resources. This

method is applied to asteroids that have assigned taxonomic classifications. An overall distribution of asteroid types and energy requirements is presented for Earth and investigated for a sample asteroid scenario. © 2022 IEEE.

Quantification Method for Rivet Hole Cracks in an Aircraft Fuselage Using Guided Waves: A BTBD-Theory-Hybrid Space-Time Cross Fusion SpatNet

Item Type Journal Article

Author H. Sun

Author Q. Feng

Author S. Huang

Author J. Li

Author L. Peng

Author S. Li

Author J. Tu

Abstract In harsh and complex aerospace environments, stress concentration causes fatigue cracks to easily form at the edges of rivet holes in an aircraft fuselage, threatening overall aircraft safety. Although testing methods based on high-order focusing ultrasonic guided waves are sensitive to cracks, there remains a lack of high-precision

quantification methods. Existing signal processing and machine learning methods have shortcomings. For example, the former cannot achieve intelligent detection and the latter has black box problems with inexplicability. To solve the above-mentioned problems, we propose a space-time cross-fusion bin-to-bin distance-theory-hybrid deep neural network (DNN) called SpatNet that combines the physical knowledge of defect quantification with a DNN to effectively detect and quantify rivet hole cracks in an aluminum alloy fuselage. In addition, we analyze the attenuation coefficients k_R, G, B and window length w_l , which can describe the degree of physical knowledge introduction, and compare the proposed SpatNet with other classical methods. The results show that the reasonable introduction of physical knowledge can effectively improve the prediction accuracy of a DNN and reduce network dependence on large-scale datasets. Related research on SpatNet based on the fusion of physical knowledge and neural network space-time cross-fusion has the potential to promote the further development of the intelligent ultrasonic testing field. © 2025 IEEE.

Abstract Background: Colon cancer ranks as the second most lethal form of cancer globally. In recent years, there has been active investigation into using the methylation profile of circulating tumor DNA (ctDNA), derived from blood, as a promising indicator for diagnosing and monitoring colon cancer. Results: We propose a liquid biopsy-based epigenetic method developed by utilizing 49 patients and 260 healthy controls methylation profile data to screen and monitor colon cancer. Our method initially identified 901 colon cancer-specific hypermethylated (CaSH) regions in the tissues of the 49 cancer patients. We then used these CaSH regions to accurately quantify the amount of circulating tumor DNA (ctDNA) in the blood samples of these same patients, utilizing cell-free DNA methylation profiles. Notably, the methylation profiles of ctDNA in the blood exhibited high sensitivity (82%) and specificity (93%) in distinguishing patients with colon cancer from the control group, with an area under the curve of 0.903. Furthermore, we confirm that our method for ctDNA quantification is effective for monitoring cancer patients and can serve as a valuable tool for postoperative prognosis. Conclusions: This study demonstrated a successful application of the quantification of ctDNA among cfDNA using the original cancer tissue-derived CaSH region for screening and monitoring colon cancer. © The Author(s) 2024.

Quantification method of tubing defects based on machine learning algorithm and magnetic flux leakage signals

Item Type Journal Article**Author** M. Shi**Author** M. Ni**Author** L. Qin**Author** Y. Liang**Author** Z. Huang

Abstract Tubing is the pipeline that transports crude oil and natural gas from the oil and gas layer to the surface of the earth. Due to the harsh operating environment, the tubing will suffer from etch pits, scratches, cracks, perforations, and even direct fractures of different degrees of defective conditions. If tubing defects are not detected and quantified in a timely manner, the continued use of tubing will result in tubing leakage and failure. Magnetic flux leakage (MFL) testing as a nondestructive testing method enables the identification and quantitative analysis of defects in metal tubing. To improve the quantification accuracy of defects in the wellhead MFL testing of tubing defects during workover operations, this paper proposes a multi-output least-squares support vector regression machine (MLSSVR) model optimized based on the simulated annealing algorithm. The size of tubing defects can be quantified by establishing the mapping between the characteristic quantity of MFL signals and the defect size. The experimental results of MFL testing of tubing defects show that the root mean square error (RMSE) of the diameter of tubing defects of the simulated annealing algorithm optimized multi-output least-squares support vector regression (SA-MLSSVR) machine model proposed in this paper is 0.4562 mm, and the RMSE of the depth of tubing defects is 0.1504 mm. Compared with the non-optimized MLSSVR model, the overall RMSE of tubing defects is reduced by 36.48%. The SA-MLSSVR model only needs one-ninth of the time to achieve the same quantification accuracy as the particle swarm optimized multi-output least-squares support vector regression machine model. © 2023 Author(s).

Abstract Ovine and bovine blood is used heavily within the development of blood-handling medical devices, such as heart pumps (left ventricular assist devices, LVADs), for which blood cell damage needs to be monitored during in vitro testing. Hematology analyzers provide cell counts but no information about cell viability. The anthraquinone DNA dyes CyTRAK Orange™ and DRAQ7™ have practical and spectral properties rendering them suitable for multicolor assays. Compared to other DNA dyes such as Vybrant Dycycle, CyTRAK Orange enables a faster staining protocol and does not require incubation at +37°C. Compared to traditional viability dyes such as propidium iodide and 7AAD, DRAQ7's unique spectral profile of excitation in both blue and red lasers and far-red emission enables identification of dual positive dead cell events and frees up detectors for use with other reagents. CyTRAK Orange and DRAQ7 could be used in combination with absolute counting bead standards to provide cell counts and viability but the combination of these dyes has previously only been used for microscopy on rodent cells. The purpose of this study was to evaluate the use of these dyes in combination in large animal blood samples for flow cytometry. A viability and cell counting protocol for bovine, ovine, and human leukocytes using CyTRAK Orange and DRAQ7 was prepared. Four different counting bead standards were evaluated using the Navios and FACSria cytometers and compared to counts obtained from hematology analyzers. CyTRAK Orange successfully detected CD45+ leukocytes in all species. The DRAQ7 single-stained dead cell counts correlated well with the CyTRAK Orange/DRAQ7 double-stained dead cell counts in human and bovine blood, but not in ovine blood, which could be related to the blood source. In conclusion, for human and bovine blood, this method works well for viability counts using different flow cytometers and bead standards. © 2016 International Society for Advancement of Cytometry. © 2016 International Society for Advancement of Cytometry

Quantification of *Actaea racemosa* L. (black cohosh) from some of its potential adulterants using qPCR and dPCR methods

Item Type Journal Article

Author J. Shanmughanandhan

Author D. Shanmughanandhan

Author S. Ragupathy

Author T.A. Henry

Author S.G. Newmaster

Abstract The demand for popular natural health products (NHPs) such as Black Cohosh is increasing considerably, which in turn challenges quality assurance (QA) throughout the supply chain. To detect and quantify the target species present in a given NHP, DNA-based molecular techniques such as Real-time quantitative PCR (qPCR) and digital PCR (dPCR) are standard tools in the food and pathogen testing industries.

There is a gap in the literature concerning validated quantitative PCR methods for botanicals that can be utilized for QA and good manufacturing practices. The objective of this study is to develop an efficient quantification method using qPCR and dPCR techniques for the detection and quantification of *Actaea racemosa* (Black cohosh) NHPs from its potential adulterants. These developed methods are validated for applicability on commercial NHPs. Species-specific hydrolysis probe assays were designed to analyze the black cohosh NHPs using qPCR and dPCR techniques. The results confirmed that the developed qPCR and dPCR methods are highly precise for identifying and quantifying black cohosh NHPs, indicating their potential applicability in future routine industrial and laboratory testing. This enables a single qPCR test to determine not only the presence of a specific botanical, but also the amount when mixed with an adulterant. © 2021, The Author(s).

Quantification of anomalies in rats' spinal cords using autoencoders

Item Type Journal Article

Author M.E. Tschuchnig

Author D. Zillner

Author P. Romanelli

Author D. Hercher**Author** P. Heimel**Author** G.J. Oostingh**Author** S. Couillard-Després**Author** M. Gadermayr

Abstract Computed tomography (CT) scans and magnetic resonance imaging (MRI) of spines are state-of-the-art for the evaluation of spinal cord lesions. This paper analyses micro-CT scans of rat spinal cords with the aim of generating lesion progression through the aggregation of anomaly-based scores. Since reliable labelling in spinal cords is only reasonable for the healthy class in the form of untreated spines, semi-supervised deviation-based anomaly detection algorithms are identified as powerful approaches. The main contribution of this paper is a large evaluation of different autoencoders and variational autoencoders for aggregated lesion quantification and a resulting spinal cord lesion quantification method that generates highly correlating quantifications. The conducted experiments showed that several models were able to generate 3D lesion quantifications of the data. These quantifications correlated with the weakly labelled true data with one model, reaching an average correlation of 0.83. We also introduced an area-based model, which correlated with a mean of 0.84. The possibility of the complementary use of the autoencoder-based method and the area feature were also discussed. Additionally to improving medical diagnostics, we anticipate features built on these quantifications to be useful for further applications like clustering into different lesions. © 2021

Quantification of Breast Arterial Calcification in Mammograms Using a UNet-Based Deep Learning for Detecting Cardiovascular Disease

Item Type Journal Article**Author** W. Li**Author** Q. Zhang**Author** D. Black**Author** H. Ding**Author** C. Iribarren**Author** A. Shojazadeh**Author** S. Molloy

Abstract Background: Breast arterial calcification (BAC) is increasingly recognized as a significant indicator of cardiovascular risk, necessitating improvements in detection and quantification methods through mammographic screening. Purpose: To develop and validate a deep-learning model capable of detecting, segmenting, and quantifying BAC in mammograms, improving mammographic screening for cardiovascular risk assessment. Materials and Methods: We conducted a retrospective study using mammograms from 369 patients. The study utilized a modified U-Net architecture that incorporates Hausdorff loss, Dice loss, and Binary Cross-Entropy (BCE) loss for segmentation and subsequent quantification. The model's performance was assessed using the Dice score, BCE loss for segmentation accuracy, linear fit, and Bland–Altman analysis for quantification accuracy. Results: Our model achieved high segmentation accuracy with Dice scores of 0.90 for the training set and 0.89 for the validation set. Quantification reliability was validated through Bland–Altman analysis, showing a mean difference of −0.98 mg of calcium in the training set. The model also demonstrated high classification accuracy with F1 scores of 0.97 and 0.93 for validation and training sets, respectively, in BAC detection. Conclusion: The deep-learning framework substantially improves BAC detection, segmentation, and quantification in mammograms, advancing the accuracy and efficiency of cardiovascular risk screening. This study supports the potential for integrated dual-purpose screening in women's healthcare. © 2025 The Association of University Radiologists

Abstract Objective: Previous studies have acknowledged the presence of eosinophilic cytoplasm in clear cell renal cell carcinoma, yet the precise quantification method and potential molecular attributes in clear cell renal cell carcinoma remain elusive. This study endeavours to precisely quantify the eosinophilic attribute and probe into the molecular mechanisms governing its presence in clear cell renal cell carcinoma. Methods: Data from cohorts of clear cell renal cell carcinoma patients who underwent nephrectomy, comprising The Cancer Genome Atlas cohort (n = 475) and Sun Yat-sen University Cancer Center cohort (n = 480), were aggregated to assess the eosinophilic attribute. Additionally, Omics data from Clinical Proteomic Tumor Analysis Consortium (CPTAC) (n = 58) were leveraged to explore the potential molecular features associated with eosinophilic clear cell renal cell carcinoma. Employing receiver operating characteristic curve analysis, the proportion of tumour cells with eosinophilic cytoplasm was determined, leading to the classification of each cohort into distinct groups: a clear group (<5%) and an eosinophilic group ($\geq 5\%$). Results: In both cohorts, the eosinophilic feature consistently correlated with higher International Society of Urological Pathology (ISUP) grade, elevated tumor stage, and the presence of necrosis. Furthermore, the Kaplan-Meier method demonstrated that patients in the eosinophilic group exhibited shorter overall survival or disease-free survival compared with those in the clear group, a pattern reaffirmed in various stratified survival analyses. Intriguingly, within The Cancer Genome Atlas cohort, the pathological characterization of cell cytoplasm (eosinophilic vs. clear) emerged as an independent risk factor for overall survival (hazard ratio = 2.507 [95% confidence interval: 1.328-4.733], $P = 0.005$) or disease-free survival (hazard ratio = 1.730 [95% confidence interval: 1.062-2.818], $P = 0.028$) via Cox regression analysis. Moreover, multi-Omics data unveiled frequent BAP1 mutations and down-regulation of Erythroblast Transformation-Specific-Related Gene associated with the eosinophilic feature in clear cell renal cell carcinoma. Additionally, patients with low expression of Erythroblast Transformation-Specific-Related Gene showed worse overall survival ($P < 0.001$). Conclusions: The quantification of the eosinophilic feature serves as a robust predictor of clinical prognosis in clear cell renal cell carcinoma. Furthermore, the manifestation of this feature may be linked to BAP1 mutations and the down-regulation of Erythroblast Transformation-Specific-Related Gene in clear cell renal cell carcinoma. Significantly, the expression levels of Erythroblast Transformation-Specific-Related Gene manifest as an exemplary prognostic marker, providing exceptional predictive accuracy for the clinical prognosis in clear cell renal cell carcinoma. © 2024 The Author(s). Quantification of fibrosis and osteosclerosis in myeloproliferative neoplasms: A computer-assisted image study

Item Type Journal Article

Abstract Evaluation of bone marrow fibrosis and osteosclerosis in myeloproliferative neoplasms (MPN) is subject to interobserver inconsistency. Performance data for currently utilized fibrosis grading systems are lacking, and classification scales for osteosclerosis do not exist. Digital imaging can serve as a quantification method for fibrosis and osteosclerosis. We used digital imaging techniques for trabecular area assessment and reticulin fiber quantification. Patients with all Philadelphia negative MPN subtypes had higher trabecular volume than controls ($p \leq 0.0015$). Results suggest that the degree of osteosclerosis helps differentiate primary myelofibrosis from other MPN. Numerical quantification of fibrosis highly correlated with subjective scores, and interobserver correlation was satisfactory. Digital imaging provides accurate quantification for osteosclerosis and fibrosis. © 2010 Elsevier Ltd.

Quantification of Flavonoid Contents in Holy Basil Using Hyperspectral Imaging and Deep Learning Approaches

Item Type Journal Article
Author A. Suratane
Author P. Chutimanukul
Author K. Plaimas

Abstract Holy basil (*Ocimum tenuiflorum* L.) is a medicinal herb rich in bioactive flavonoids with therapeutic properties. Traditional quantification methods rely on time-consuming and destructive extraction processes, whereas hyperspectral imaging provides a rapid, non-destructive alternative by analysing spectral signatures. However, effectively linking hyperspectral data to flavonoid levels remains a challenge for developing early detection tools before harvest. This study integrates deep learning with hyperspectral imaging to quantify flavonoid contents in 113 samples from 26 Thai holy basil cultivars collected across diverse regions of Thailand. Two deep learning architectures, ResNet1D and CNN1D, were evaluated in combination with feature extraction techniques, including wavelet transformation and Gabor-like filtering. ResNet1D with wavelet transformation achieved optimal performance, yielding an area under the receiver operating characteristic curve (AUC) of 0.8246 and an accuracy of 0.7702 for flavonoid content classification. Cross-validation demonstrated the model's robust predictive capability in identifying antioxidant-rich samples. Samples with the highest predicted flavonoid content were identified, and cultivars exhibiting elevated levels of both flavonoids and phenolics were highlighted across various regions of Thailand. These findings demonstrate the predictive capability of hyperspectral data combined with deep learning for phytochemical assessment. This approach offers a valuable tool for non-destructive quality evaluation and supports cultivar selection for higher phytochemical content in breeding programs and agricultural applications. © 2025 by the authors.

Abstract Background: Hematoma and perihematoma edema volumes are important radiographic markers in spontaneous intracerebral hemorrhage. Accurate, reliable, and efficient quantification of these volumes will be paramount to their utility as

measures of treatment effect in future clinical studies. Both manual and semi-automated quantification methods of hematoma and perihematoma edema volumetry are time-consuming and susceptible to inter-rater variability. Efforts are now underway to develop a fully automated algorithm that can replace them. A (QUANTUM) study to establish inter-quantification method measurement equivalency, which deviates from the traditional use of measures of agreement and a comparison hypothesis testing paradigm to indirectly infer quantification method measurement equivalence, is described in this article. The Quantification of Hematoma and Perihematoma Edema Volumes in Intracerebral Hemorrhage study aims to determine whether a fully automated quantification method and a semi-automated quantification method for quantification of hematoma and perihematoma edema volumes are equivalent to the hematoma and perihematoma edema volumes of the manual quantification method. Methods/Design: Hematoma and perihematoma edema volumes of supratentorial intracerebral hemorrhage on 252 computed tomography scans will be prospectively quantified in random order by six raters using the fully automated, semi-automated, and manual quantification methods. Primary outcome measures for hematoma and perihematoma edema volumes will be quantified via computed tomography scan on admission (<24 h from symptom onset) and on day 3 (72 ± 12 h from symptom onset), respectively. Equivalence hypothesis testing will be conducted to determine if the hematoma and perihematoma edema volume measurements of the fully automated and semi-automated quantification methods are within 7.5% of the hematoma and perihematoma edema volume measurements of the manual quantification reference method. Discussion: By allowing direct equivalence hypothesis testing, the Quantification of Hematoma and Perihematoma Edema Volumes in Intracerebral Hemorrhage study offers advantages over radiology validation studies which utilize measures of agreement to indirectly infer measurement equivalence and studies which mistakenly try to infer measurement equivalence based on the failure of a comparison two-sided null hypothesis test to reach the significance level for rejection. The equivalence hypothesis testing paradigm applied to artificial intelligence application validation is relatively uncharted and warrants further investigation. The challenges encountered in the design of this study may influence future studies seeking to translate artificial intelligence medical technology into clinical practice. © The Author(s) 2022.

Quantification of heterogeneity as a biomarker in tumor imaging: A systematic review

Item Type Journal Article

Author L. Alic

Author W.J. Niessen

Author J.F. Veenland

Abstract Background: Many techniques are proposed for the quantification of tumor heterogeneity as an imaging biomarker for differentiation between tumor types, tumor grading, response monitoring and outcome prediction. However, in clinical practice these methods are barely used. This study evaluates the reported performance of the described methods and identifies barriers to their implementation in clinical practice. Copyright:; Methodology: The Ovid, Embase, and Cochrane Central databases were searched up to 20 September 2013. Heterogeneity analysis methods were classified into four categories, i.e., non-spatial methods (NSM), spatial grey level methods (SGLM), fractal analysis (FA) methods, and filters and transforms (F&T). The performance of the different methods was compared.; Principal Findings: Of the 7351 potentially relevant publications, 209 were included. Of these studies, 58% reported the use of NSM, 49% SGLM, 10% FA, and 28% F&T. Differentiation between tumor types, tumor grading and/or outcome prediction was the goal in 87% of the studies. Overall, the reported area under the curve (AUC) ranged from 0.5 to 1 (median 0.87). No relation was found between the performance and the quantification methods used, or between the performance and the imaging modality. A negative correlation was found between the tumor-feature ratio and the AUC, which is presumably caused by overfitting in small datasets. Cross-validation was reported in 63% of the classification studies. Retrospective analyses were conducted in 57% of the studies without a clear description.; Conclusions: In a research setting, heterogeneity quantification methods can differentiate between tumor types, grade tumors, and predict outcome and monitor treatment effects. To translate these methods to clinical practice, more prospective studies are required that use external datasets for

validation: these datasets should be made available to the community to facilitate the development of new and improved methods. © 2014 Alic et al.

Abstract Being water flooded for more than 6 decades, the Lasaxing Oilfield in Daqing is now developing in the extra-high water cut period and the ineffective water circulation (IWC) worsens year by year. Due to the heterogeneity and the gravity effect, there always exists high permeability channels at the bottom of the thick reservoir, which affects the water flooding efficiency greatly. As to the quantification of the IWC in thick reservoir, a novel method based on machine learning is promoted in this paper. Firstly, the reservoir classification model based on machine learning is given. 7 parameters of 60000 well-layer samples of the typical block are analyzed by means of PCA, and the clustering model is then constructed based on K-Means and manual intervention. The reservoir is then classified into 9 categories according to the interlayer position, the reservoir thickness, the reservoir permeability and etc. Secondly, the quantification method of the IWC in thick reservoir based on inspecting wells and machine learning is promoted. The reservoirs with highly water flooded section, which implies the IWC thickness, are taken as learning samples. The method of SVM and KNN is selected in the model training, which lead to a conformity rate of 75%. Thirdly, the method promoted is implemented in typical well groups, which shows that the percentage of ineffective thickness is 20–60%. The low-price and high-efficient profile controlling agent is then used in the stimulation pilot, which lead to an oil increasing of 3890t. The methodology promoted in this paper has the advantage of practical, short time of evaluating and easy-to-use, and presents an effective in the identification of the IWC. The method could also be used in other similar oilfields, which offers valuable reference for the effective development of a mature field at the extra-high water cut period. © 2022, The Author(s), under exclusive license to Springer Nature Singapore Pte Ltd.

Quantification of Large Transmural Biopsies Reveals Heterogeneity in Innervation Patterns in Chronic Myocardial Infarction

Item Type Journal Article

Abstract Background: Abnormal cardiac innervation plays an important role in arrhythmogenicity after myocardial infarction (MI). Data regarding reperfusion models and innervation abnormalities in the medium to long term after MI are sparse. Histologic quantification of the small-sized cardiac nerves is challenging, and transmural analysis has not been performed. Objectives: This study sought to assess cardiac innervation patterns in transmural biopsy sections in a porcine reperfusion model of MI (MI-R) using a novel method for nerve quantification. Methods: Transmural biopsy sections from 4 swine (n = 83) at 3 months after MI-R and 3 controls (n = 38) were stained with picrosirius red (fibrosis) and beta-III-tubulin (autonomic nerves). Biopsy sections were classified as infarct core, border zone, or remote zone. Each biopsy section was analyzed with a custom software pipeline, allowing calculation of nerve density and classification into innervation types at the 1 × 1-mm resolution level. Relocation of the classified squares to the original biopsy

position enabled transmural quantification and innervation heterogeneity assessment. Results: Coexisting hyperinnervation, hypoinnervation, and denervation were present in all transmural MI-R biopsy sections. The innervation heterogeneity was greatest in the infarct core (median: 0.14; IQR: 0.12-0.15), followed by the border zone (median: 0.05; IQR: 0.04-0.07; $P = 0.02$) and remote zone (median: 0.02; IQR: 0.02-0.03; $P < 0.0001$). Only in the border zone was a positive linear relation between fibrosis and innervation heterogeneity observed ($R = 0.79$; $P < 0.0001$). Conclusions: This novel method allows quantification of nerve density and heterogeneity in large transmural biopsy sections. In the chronic phase after MI-R, alternating innervation patterns were identified within the same biopsy section. Persistent innervation heterogeneity, in particular in the border zone biopsy sections, may contribute to late arrhythmogenicity. © 2023 American College of Cardiology Foundation

Quantification of Left Atrium Fibrosis from LGE MRI in Atrial Fibrillation

Item Type Conference Paper

Author A. Andalo

Author C. Fabbri

Author A. Masci

Author C. Corsi

Abstract Late gadolinium enhanced magnetic resonance imaging (LGE-MRI) is a recent technique used for fibrosis distribution assessment in the left atrium (LA) wall. Unfortunately, LGE-MRI analysis does not rely on a standardized image processing protocol. The aim of the study was to compare different methods to quantify fibrosis in the LA in the 3D domain. LGE-MRI from 60 AF patients were analyzed applying five different approaches for fibrosis segmentation: an histogram-based (H-6SD), the image intensity ratio (IIR), the blood pool normalization (BP), the Chan-Vese (CV) and the graph-cut (GC) method. For each method we quantified the percentage of fibrosis with respect to the entire LA wall mass. Results showed these five approaches can be divided in two groups; the group composed by the H-6SD, CV and GC is characterized similar results (mean coefficient of variation =0.3), while the results obtained applying BP and IIR strongly depend on the quality of the acquisition (mean coefficient of variation=0.62). Utah stage classification resulted in a wide disagreement (22/60 patients, 37%) among BP and IIR. The two approaches which best matched the Utah classification were the CV and GC (49/60 patients, 82%). This study confirmed the evaluation of the quantification method appears critical and further research is needed to define a satisfactory standard for atrial fibrosis segmentation. © 2018 Creative Commons Attribution.

Abstract Magnetic Resonance Spectroscopic Imaging (MRSI) is a clinical imaging modality for measuring tissue metabolite levels in-vivo. An accurate estimation of spectral parameters allows for better assessment of spectral quality and metabolite concentration levels. The current gold standard quantification method is the LCModel - a commercial fitting tool. However, this fails for spectra having poor signal-to-noise ratio (SNR) or a large number of artifacts. This paper introduces a framework based on random forest regression for accurate estimation of the output parameters of a model based analysis of MR spectroscopy data. The goal of our proposed framework is to learn the spectral features from a training set comprising of different variations of both simulated and in-vivo brain spectra and then use this learning for the subsequent metabolite quantification. Experiments involve training and testing on simulated and in-vivo human brain spectra. We estimate parameters such as concentration of metabolites and compare our results with that from the LCModel. © Springer International Publishing AG 2017.

Abstract The aim of this study was to quantify pancreatic exocrine function in normal subjects and in patients with chronic pancreatitis (CP) before and after pancreatic duct drainage procedures (PDDP) with dynamic secretin-enhanced magnetic resonance (MR) cholangiopancreatography (S-MRCP). Pancreatic exocrine secretions [quantified by pancreatic flow output (PFO) and total excreted volume (TEV)] were quantified twice in ten healthy volunteers and before and after treatment in 20 CP patients (18 classified as severe, one as moderate, and one as mild according to the Cambridge classification). PFO and TEV were derived from a linear regression between MR-calculated volumes and time. In all subjects, pancreatic exocrine fluid

volume initially increased linearly with time during secretin stimulation. In controls, the mean PFO and TEV were 6.8 ml/min and 97 ml; intra-individual deviations were 0.8 ml/min and 16 ml. In 10/20 patients with impaired exocrine secretions before treatment, a significant increase of PFO and TEV was observed after treatment ($P<0.05$); 3/20 patients presented post-procedural acute pancreatitis and a reduced PFO. The S-MRCP quantification method used in the present study is reproducible and provides normal values for PFO and TEV in the range of those obtained from previous published intubation studies. The initial results in CP patients have demonstrated non-invasively a significant short-term improvement of PFO and TEV after PDDP. © Springer-Verlag 2005.

Quantification of pass plays based on geometric features of formations in team sports

Item Type Conference Paper

Author T. Mimura

Author Y. Nakada

Abstract In recent years, geometric features of formations such as players' dominant regions and their adjacency have been frequently computed and utilized for team sports' analysis. Such geometric features of formations have also been successfully applied to real game data in many team sports. In this paper, we propose a novel quantification method of pass plays by combining multiple geometric features of formations from two viewpoints: (i) effectiveness of leading to a shoot, and (ii) risk of being robbed a ball. The proposed method extracts many feature values including passers' and receivers' geometric feature values and then constructs quantification models from the two viewpoints based on statistical classification methods using the extracted feature values. Thus, the proposed method enables users to effectively understand pass plays and tactics used through visualization tools of players and ball position data. For validation, this method is applied to real players' position data during a soccer game. © 2019 Copyright is held by the owner/author(s).

Editor Leif R.C.

Abstract We present a cell image quantification method for image-based drug response prediction from patient-derived glioblastoma cells. Drug response of each person differs at the cellular level. Therefore, quantification of a patient-derived cell phenotype is important in drug response prediction. We performed fluorescence microscopy to understand the features of patient-derived 3D cancer spheroids. A 3D cell culture simulates the in-vivo environment more closely than 2D adherence culture, and thus, allows more accurate cell analysis. Furthermore, it allows assessment of cellular aggregates. Cohesion is an important feature of cancer cells. In this paper, we demonstrate image-based quantification of cellular area, fluorescence intensity, and cohesion. To this end, we first performed image stitching to create an image of each well of the plate with the same environment. This image shows colonies of various sizes and shapes. To automatically detect the colonies, we used an intensity based classification algorithm. The morphological features of each cancer cell colony were measured. Next, we calculated the location correlation of each colony that is appeal of the cell density in the same well environment. Finally, we compared the features for drug-treated and untreated cells. This technique could potentially be applied for drug screening and quantification of the effects of the drugs. © 2017 SPIE.

Quantification of play behaviour in calves using automated ultra-wideband location data and its association with age, weaning and health status

Item Type Journal Article**Author** J.A. Vázquez-Diosdado**Author** C. Doidge**Author** E.V. Bushby**Author** F. Occhiuto**Author** J. Kaler

Abstract Play behaviour can act as an indicator of positive animal welfare. Previous attempts to predict play behaviour in farmed calves are limited because of the classification methods used, which lead to overestimation, and the short time periods that calves are observed. The study aimed to automatically classify and quantify play behaviour in farmed calves using location data from ultra-wide band sensors and to investigate factors associated with play behaviour. Location data were collected from 46 calves in three cohorts for a period of 18 weeks. Behavioural observations from video footage were merged with location data to obtain a total of 101.36 h of labelled data. An AdaBoost ensemble learning algorithm was implemented to classify play behaviour. To account for overestimation, generally seen in low-prevalence behaviours, an adjusted count technique was applied to the outputs of the classifier. Two generalized linear mixed models were fitted to investigate factors (e.g. age, health) associated with duration of play and number of play instances per day. Our algorithm identified play behaviour with > 94% accuracy when evaluated on the test set with no animals used for training, and 16% overestimation, which was computed based on the predicted number of samples of play versus the number of samples labelled as play on the test set. The instances and duration of play behaviour per day significantly decreased with age and sickness, whilst play behaviour significantly increased during and after weaning. The instances of play also significantly decreased as mean temperature increased. We suggest that the quantification method that we used could be used to detect and monitor other low prevalence behaviours (e.g. social grooming) from location data, including indicators of positive welfare. © The

Abstract Objectives: To determine if quantifying Gleason pattern 4 (GP4) is superior to Grade Group (GG) in predicting any and distant metastatic recurrence after radical prostatectomy (RP) for prostate cancer, and compare various GP4 quantification

methods for predicting metastatic recurrence using preoperative targeted biopsy and magnetic resonance imaging (MRI) data. Patients and Methods: We conducted a retrospective study of patients who underwent MRI-guided biopsies and RP from 2009 to 2018. Patients with GG 2–4 without GP5 disease on biopsy and/or RP specimen were included. The predictors compared were biopsy GG, percentage of GP4 in biopsy cores, millimetres of GP4 in biopsy cores, and volume of GP4 based on MRI lesion volume. These methods were also compared to the Cancer of the Prostate Risk Assessment (CAPRA), International Staging Collaboration for Cancer of the Prostate (STAR-CAP), European Association of Urology (EAU), and National Comprehensive Cancer Network (NCCN) risk classifications. The C-index for each model was calculated to evaluate discrimination performance. Results: A total of 446 patients were analysed, with a median follow-up of 6.9 years for patients without an event; 46 patients developed any metastasis. For any metastatic recurrence based on biopsy findings, the CAPRA score (C-Index = 0.72) showed the highest discrimination among risk scores, surpassing biopsy GG (C-Index = 0.70), but was outperformed by percentage GP4 (C-Index = 0.74), millimetres GP4 (C-Index = 0.77), and volume of GP4 (C-Index = 0.80). Conclusion: For patients with GG 2–4 prostate cancer containing GP4, preoperative GP4 volume estimation using MRI and targeted biopsy outperforms Gleason scoring classification and standard risk scores in predicting any and distant metastatic recurrence. Further research is warranted on the best methods to quantify GP4 before incorporation in treatment decision-making. © 2025 The Author(s). Quantification of sulfate-reducing bacteria in industrial wastewater, by real-time polymerase chain reaction (PCR) using *dsrA* and *apsA* genes

Item Type Journal Article

Author E. Ben-Dov

Author A. Brenner

Author A. Kushmaro

Abstract Real-time polymerase chain reaction (PCR) is considered a highly sensitive method for the quantification of microbial organisms in environmental samples. This study was conducted to evaluate real-time PCR with SybrGreen detection as a quantification method for sulfate-reducing bacteria (SRB) in industrial wastewater produced by several chemical industries. We designed four sets of primers and developed standard curves based on genomic DNA of *Desulfovibrio vulgaris* from pure culture and on plasmids containing dissimilatory sulfate reductase (*dsrA*) or adenosine-5'-phosphosulfate reductase (*apsA*) genes of SRB. All the standard curves, two for *dsrA* and two for *apsA* genes, had a linear range between 0.95×10^2 and 9.5×10^6 copies/ μL and between 1.2×10^3 and 1.2×10^7 copies/ μL , respectively. The theoretical copy numbers of the tenfold dilutions of *D. vulgaris* genomic DNA were best estimated (between 2.7 to 10.5 times higher than theoretical numbers) by the standard curve with DSR1F and RH3-dsr-R primers. To mimic the effect of foreign DNA in environmental samples, serial dilutions of *D. vulgaris* genomic DNA were mixed with *Escherichia coli* chromosomal DNA (40 ng per assay). This influenced neither PCR amplification nor the quantification of target DNA. Industrial wastewater was sampled during a 15-month period and analyzed for the presence of SRB, based on *dsrA* gene amplification. SRB displayed a higher abundance during the summer

(about 107-108 targets mL⁻¹) and lower during the winter (about 104-105 targets mL⁻¹). The results indicate that our real-time PCR approach can be used for detection of uncultured SRB and will provide valuable information related to the abundance of SRB in durable environmental samples, such as complex and saline industrial wastewaters. © 2007 Springer Science+Business Media, LLC.

Abstract Introduction The evaluation of tongue colour has been an important approach to examine human health in Kampo medicine (traditional Japanese medicine) because the change in tongue colour may suggest physical or mental disorders. Several tongue colour quantification methods have been published to objectify clinical information among East Asian countries. However, reliable tongue colour analysis results among Japanese test persons are limited because of a lack of quantitative evaluation of tongue colour. We aimed to use advances in digital imaging processing to quantify and verify clinical data tongue colour diagnosis by characterising differences in tongue features. Methods The DS01-B tongue colour information acquisition system was used to extract tongue images of 1080 Japanese test subjects. Evaluation of tongue colour, body and coating was performed by 10 experienced Kampo medicine physicians. The acquired images were classified into five tongue body colour categories and six tongue coating colour categories based on evaluations from 10 physicians with extensive Kampo medicine experience. K-means clustering algorithm was applied as a machine learning (the study of pattern recognition by computational learning) method to the acquired images to quantify tongue body and coating colour information. Results Tongue body (n = 550) and tongue coating (n = 516) colour samples were classified and analysed. Clusters consisting of five tongue body colour categories and six tongue coating colour categories were experimentally described in the CIELAB colour space. Statistical differences were evident among the clinically primary tongue colours. Conclusions Clinically important tongue colour differences in Kampo medicine can be visualised by applying machine learning to tongue images taken under stable conditions. This has implications for developing globally unified, reliable tongue colour diagnostic criteria which could be used to explore the relevance between clinical status and tongue colour. © 2016 The Author(s)

Abstract Aims: Develop quantitative assays (qPCR) to determine the detection threshold limits, colonization and persistence of *Trichoderma gamsii*, *Trichoderma afroharzianum* and *T. harzianum* inoculants in cropping soils, the wheat rhizosphere and their in planta suppressive efficacy against the crown rot pathogen *Fusarium pseudograminearum*. Methods and Results: *Trichoderma* qPCR primers were designed from the internal transcribed spacer region of 5.8S rDNA and from sequences of DNA fragments diagnostic for each inoculant genotype. The minimum detection thresholds of qPCR assays varied between 1×10^3 (log 3) and 8×10^4 (log 4.9) conidia (genome) equivalents per gram of soil for multi- and single-copy target sequences, respectively and were independent of soil type. There was a strong correlation ($r^2 = 0.974$) between culture-dependent and culture-independent (qPCR) quantification methods. In wheat bioassays, *Trichoderma* inoculants colonized rhizosphere soils and wheat roots at 56–112 days postemergence to a depth of 20 cm but were more abundant ($P < 0.001$) at 0–10 cm root depth, means ranging from 2×10^2 (log 2.3) to 4×10^5 (log 5.6) conidia equivalents per gram of rhizosphere soil or root tissue. Inoculants reduced ($P < 0.001$) *F. pseudograminearum* biomass in wheat crown and root tissue by up to 5754-fold and increased ($P = 0.008$) plant biomass, relative to the pathogen control. Conclusions: The qPCR assays provided sensitive and accurate assessment of wheat root and rhizosphere soil colonization of *Trichoderma* inoculants. Strains persisted through to grain maturity at levels shown to significantly suppress *F. pseudograminearum* in planta. Significance and Impact of the Study: The qPCR assays developed here were used to determine the wheat rhizosphere dynamics of *T. harzianum*, *T. afroharzianum* and *T. gamsii* inoculants and their suppressive efficacy against *F. pseudograminearum* in planta. These assays can

be applied to monitor inoculant dynamics in suppressing crown rot and other wheat root diseases in the field. © 2020 The Society for Applied Microbiology

Abstract This study investigates key performance indicators (KPIs) influencing physical jumping performance in elite-level female volleyball players. This study aims to investigate three hypotheses: (1) the quantification of training load with “Stress Training Response” score is better in explaining and predicting jump performance than classic quantification methods such as mean or sum, (2) high intense exercises stand as primary variables explaining jump performance, and (3) non-linear models are better than linear models to explain and predict jump performance. Nineteen elite-level female volleyball players were monitored over a 190-day season. Various training-related parameters, including workload (external and internal) quantification, player positions, and menstrual cycle data, were collected. Machine learning techniques were employed to analyse and predict jump performance based on these variables. The Random Forest model outperformed other models in describing jump performance ($R^2 = 0.64$). Key performance indicators identified included workload dynamics, age, and the percentage of intense jumps made during the season. Prediction on a new dataset demonstrated promising results (Mean Absolute Error (MAE) = 4.95 cm (Confidence Interval (CI) 4.56 cm and 5.42 cm), $R^2 = 0.55$ (CI 0.45 and 0.62)). Findings suggest that intense training prior to performance enhances jump performance, with older players exhibiting superior jumping performance. © 2024 Cardiff Metropolitan University.

Abstract Quantification is the supervised machine learning task that estimates the class distribution in a sample. Therefore, quantification applications typically involve predicting aggregated quantities, such as the prevalence of positive comments about a product, personality or company on a set of social media posts. However, quantification analysis is more informative when performed over time, such as when we are interested in tracking public opinion on social media and relating changes in opinion with relevant events. The vast majority of the literature considers quantification as a standalone task, assuming the output of quantifiers to be independent even when applied to temporal data. This paper proposes a new quantification task, Quantification over Time (QoT), that allies quantification with time series forecasting methods. We propose an approach based on the Kalman filter, which can help improve the performance of standalone quantifications and a general framework that includes both ours and SOTA methods. In an experimental comparison with several textual datasets and numeral datasets, we show that our method outperforms existing methods for QoT in the literature, such as a simple composition of the classify and count method with moving averages and ReadMe2 as a standalone quantifier. We also show that our proposal can outperform several baselines, including recently proposed quantifiers used as standalone approaches. Abstract In many applications there is a need to monitor how a population is distributed across different classes, and to track the changes in this distribution that derive from varying circumstances, an example such application is monitoring the percentage (or "prevalence") of unemployed people in a given region, or in a given age range, or at different time periods. When the membership of an individual in a class cannot be established deterministically, this monitoring activity requires classification. However, in the above applications the final goal is not determining which class each individual belongs to, but simply estimating the prevalence of each class in the unlabeled data. This task is called quantification. In a supervised learning framework we may estimate the distribution across the classes in a test set from a training set of labeled

individuals. However, this may be sub optimal, since the distribution in the test set may be substantially different from that in the training set (a phenomenon called distribution drift). So far, quantification has mostly been addressed by learning a classifier optimized for individual classification and later adjusting the distribution it computes to compensate for its tendency to either under-or over-estimate the prevalence of the class. In this paper we propose instead to use a type of decision trees (quantification trees) optimized not for individual classification, but directly for quantification. Our experiments show that quantification trees are more accurate than existing state-of-the-art quantification methods, while retaining at the same time the simplicity and understandability of the decision tree framework. © 2013 IEEE.

Quantification under prior probability shift: The ratio estimator and its extensions

Item Type Journal Article

Author A.F. Vaz

Author R. Izbicki

Author R.B. Stern

Abstract The quantification problem consists of determining the prevalence of a given label in a target population. However, one often has access to the labels in a sample from the training population but not in the target population. A common assumption in this situation is that of prior probability shift, that is, once the labels are known, the distribution of the features is the same in the training and target populations. In this paper, we derive a new lower bound for the risk of the quantification problem under the prior shift assumption. Complementing this lower bound, we present a new approximately minimax class of estimators, ratio estimators, which generalize several previous proposals in the literature. Using a weaker version of the prior shift assumption, which can be tested, we show that ratio estimators can be used to build confidence intervals for the quantification problem. We also extend the ratio estimator so that it can: (i) incorporate labels from the target population, when they are available and (ii) estimate how the prevalence of positive labels varies according to a function of certain covariates. © 2019 Afonso Fernandes Vaz, Rafael Izbicki and Rafael Bassi Stern.

Quantification using permutation-invariant networks based on histograms

Item Type Journal Article

Author O. Pérez-Mon

Author A. Moreo

Author J.J.D. Coz

Author P. González

Abstract Quantification, also known as class prevalence estimation, is the supervised learning task in which a model is trained to predict the prevalence of each class in a given bag of examples. This paper investigates the application of deep neural networks for tasks of quantification in scenarios where it is possible to apply a symmetric supervised approach that eliminates the need for classification as an intermediate step, thus directly addressing the quantification problem. Additionally, it discusses existing permutation-invariant layers designed for set processing and assesses their suitability for quantification. Based on our analysis, we propose HistNetQ, a novel neural architecture that relies on a permutation-invariant representation based on histograms that is especially suited for quantification problems. Our experiments carried out in two standard competitions, which have become a reference in the quantification field, show that HistNetQ outperforms other deep neural network architectures designed for set processing, as well as the current state-of-the-art quantification methods. Furthermore, HistNetQ offers two significant advantages over traditional quantification methods: i) it does not require the labels of the training examples but only the prevalence values of a collection of training bags, making it applicable to new scenarios; and ii) it is able to optimize any custom quantification-oriented loss function. © The Author(s) 2024.

Quantification via gaussian latent space representations

Item Type Journal Article

Author O. Pérez-Mon

Author J. José del Coz

Author P. González

Abstract Quantification, or prevalence estimation, is the task of predicting the prevalence of each class within an unknown bag of examples. Most existing quantification methods in the literature rely on prior probability shift assumptions to create a quantification model that uses the predictions of an underlying classifier to make optimal prevalence estimates. In this work, we present an end-to-end neural network that uses Gaussian distributions in latent spaces to obtain invariant representations of bags of examples. This approach addresses the quantification problem using deep learning, enabling the optimization of specific loss functions relevant to the problem and avoiding the need for an intermediate classifier, tackling the quantification problem as a direct optimization problem. Our method achieves state-of-the-art results, both against traditional quantification methods and other deep learning approaches for quantification. The code needed to reproduce all our experiments is publicly available at <https://github.com/AICGijon/gmnet>. © 2026 The Authors. Published by Elsevier Ltd. Quantification-oriented learning based on reliable classifiers

Item Type Journal Article

Author J. Barranquero

Author J. Díez

Author J. José Del Coz

Abstract Real-world applications demand effective methods to estimate the class distribution of a sample. In many domains, this is more productive than seeking individual predictions. At a first glance, the straightforward conclusion could be that this task, recently identified as quantification, is as simple as counting the predictions of a classifier. However, due to natural distribution changes occurring in real-world problems, this solution is unsatisfactory. Moreover, current quantification models based on classifiers present the drawback of being trained with loss functions aimed at classification rather than quantification. Other recent attempts to address this issue suffer certain limitations regarding reliability, measured in terms of classification abilities. This paper presents a learning method that optimizes an alternative metric that combines simultaneously quantification and classification performance. Our proposal offers a new framework that allows the construction of binary quantifiers that are able to accurately estimate the proportion of positives, based on models with reliable classification abilities. © 2014 Elsevier Ltd. Author J.J. del Coz

Abstract QuantificationLib is an open-source Python library that provides a comprehensive set of algorithms for quantification learning. Quantification, also known as prevalence estimation, is a supervised machine-learning task where the objective is to train a model that is able to predict the distribution of classes in a set of unseen examples or bags. This library offers a wide variety of quantification methods suited for easy prototyping and experimentation, applicable to a wide range of quantification applications. © 2024 The Authors

Quantified groundwater–surface water dynamics across Tigris–Euphrates basin through integrated modelling

Item Type Journal Article**Author** Q. Alkhawlan**Author** S. Algburi**Author** S. Sabeeh**Author** M. Alsubih**Author** S. Islam**Author** R. Abad Khan

Abstract Water scarcity in Iraq's Tigris–Euphrates basin is intensifying under climate change, upstream regulation, and increasing demand, creating pressure on groundwater and surface water sustainability. This study develops an integrated framework that merges Gravity Recovery and Climate Experiment groundwater anomalies, Global Land Data Assimilation System soil moisture fields, Moderate Resolution Imaging Spectroradiometer evapotranspiration, hydrometric observations, and machine learning to quantify groundwater–surfacewater exchanges. An extreme gradient boosting model predicts groundwater levels with R^2 of 0.92 and root mean square error of 0.15 m. Results indicate groundwater storage declines ranging from -1.4 cm year $^{-1}$ in the north to -0.9 cm year $^{-1}$ in the south during 2002–2023, with seasonal deficits amplifying depletion. Exchange flux analysis reveals groundwater discharge sustaining rivers during droughts and flood-induced recharge during high flows. Scenario projections to 2050 show moderated depletion under RCP4.5 but accelerated decline under RCP8.5, emphasizing the need for adaptive abstraction

control and managed recharge strategies. © 2026 IAHS.

Abstract Consciousness remains a multifaceted phenomenon that is difficult to be measured by traditional quantification methods. Here we propose the intrinsic probability density function (iPDF) as a quantitative method to evaluate the dynamic inter-cortical interactions that underlie conscious states. First, the method utilizes empirical mode decomposition to derive intrinsic mode functions (IMFs) from EEG signals. Then, the method generates scale-dependent probability density functions for successive partial sums of IMFs that can capture subtle variations in neural modulation patterns. We tested the iPDF analysis across various consciousness states such as general anesthesia, distinct sleep stages (wakefulness, REM, and deep sleep), sensory conditions (eyes open versus eyes closed), and between dementia patients and healthy subjects. Our findings reveal that active neural interactions or modulations during wakefulness and REM sleep are characterized by super-Gaussian iPDF patterns. By contrast, the reduced interactions observed in anesthesia and deep sleep yield near-Gaussian iPDF profiles. We also present a classification model built on iPDF features that achieved an accuracy of approximately 87 % in distinguishing dementia patients from health controls, demonstrating the iPDF as a potential biomarker in clinical screening. This study supports the idea that consciousness emerges from complex, scale-dependent neural processes and presents a robust, quantitative framework that may enhance both our theoretical understanding and practical assessment of various states of consciousness. © 2025 The Authors

Quantifying construction and demolition waste: An analytical review

Item Type Journal Article**Author** Z. Wu**Author** A.T.W. Yu**Author** L. Shen**Author** G. Liu

Abstract Quantifying construction and demolition (C&D) waste generation is regarded as a prerequisite for the implementation of successful waste management. In literature, various methods have been employed to quantify the C&D waste generation at both regional and project levels. However, an integrated review that systemically describes and analyses all the existing methods has yet to be conducted. To bridge this research gap, an analytical review is conducted. Fifty-seven papers are retrieved based on a set of rigorous procedures. The characteristics of the selected papers are classified according to the following criteria - waste generation activity, estimation level and quantification methodology. Six categories of existing C&D waste quantification methodologies are identified, including site visit method, waste generation rate method, lifetime analysis method, classification system accumulation method, variables modelling method and other particular methods. A critical comparison of the identified methods is given according to their characteristics and implementation constraints. Moreover, a decision tree is proposed for aiding the selection of the most appropriate quantification method in different scenarios. Based on the analytical review, limitations of previous studies and recommendations of potential future research directions are further suggested. © 2014 Elsevier Ltd.

Quantifying counts and costs via classification

Item Type Journal Article

Author G. Forman

Abstract Many business applications track changes over time, for example, measuring the monthly prevalence of influenza incidents. In situations where a classifier is needed to identify the relevant incidents, imperfect classification accuracy can cause substantial bias in estimating class prevalence. The paper defines two research challenges for machine learning. The 'quantification' task is to accurately estimate the number of positive cases (or class distribution) in a test set, using a training set that may have a substantially different distribution. The 'cost quantification' variant estimates the total cost associated with the positive class, where each case is tagged with a cost attribute, such as the expense to resolve the case. Quantification has a very different utility model from traditional classification research. For both forms of quantification, the paper describes a variety of methods and evaluates them with a suitable methodology, revealing which methods give reliable estimates when training data is scarce, the testing class distribution differs widely from training, and the positive class is rare, e.g., 1% positives. These strengths can make quantification practical for business use, even where classification accuracy is poor. © 2008 Springer Science+Business Media, LLC.

Quantifying COVID-19 Content in the Online Health Opinion War Using Machine Learning

Abstract A huge amount of potentially dangerous COVID-19 misinformation is appearing online. Here we use machine learning to quantify COVID-19 content among online opponents of establishment health guidance, in particular vaccinations ('anti-vax'). We find that the anti-vax community is developing a less focused debate around

COVID-19 than its counterpart, the pro-vaccination ('pro-vax') community. However, the anti-vax community exhibits a broader range of 'flavors' of COVID-19 topics, and hence can appeal to a broader cross-section of individuals seeking COVID-19 guidance online, e.g. individuals wary of a mandatory fast-tracked COVID-19 vaccine or those seeking alternative remedies. Hence the anti-vax community looks better positioned to attract fresh support going forward than the pro-vax community. This is concerning since a widespread lack of adoption of a COVID-19 vaccine will mean the world falls short of providing herd immunity, leaving countries open to future COVID-19 resurgences. We provide a mechanistic model that interprets these results and could help in assessing the likely efficacy of intervention strategies. Our approach is scalable and hence tackles the urgent problem facing social media platforms of having to analyze huge volumes of online health misinformation and disinformation. © 2013 IEEE.

Quantifying Deep Learning Model Uncertainty in Conformal Prediction

Item Type Conference Paper

Author H. Karimi

Author R. Samavi

Editor Soh H.

Editor Geib C.

Editor Petrick R.

Abstract Precise estimation of predictive uncertainty in deep neural networks is a critical requirement for reliable decisionmaking in machine learning and statistical modeling, particularly in the context of medical AI. Conformal Prediction (CP) has emerged as a promising framework for representing the model uncertainty by providing well-calibrated confidence levels for individual predictions. However, the quantification of model uncertainty in conformal prediction remains an active research area, yet to be fully addressed. In this paper, we explore state-of-the-art CP methodologies and their theoretical foundations. We propose a probabilistic approach in quantifying the model uncertainty derived from the produced prediction sets in conformal prediction and provide certified boundaries for the computed uncertainty. By doing so, we allow model uncertainty measured by CP to be compared by other uncertainty quantification methods such as Bayesian (e.g., MC-Dropout and DeepEnsemble) and Evidential approaches. © 2023, Association for the Advancement of Artificial Intelligence (www.aaai.org). Quantifying Elevation Changes Under Engineering Measures Using
Multisource Remote Sensing and Interpretable Machine Learning: A Case
Study of the Chinese Loess Plateau

Item Type Journal Article**Author** S. Zhou**Author** Q. Zhu**Author** S. Li

Abstract Highlights: What are the main findings? Interpretable machine learning models identify the relative importance and spatial patterns of environmental and anthropogenic factors affecting elevation change. What are the implications of the main findings? The transparent analytical framework supports land management and targeted implementation of erosion control measures on the Loess Plateau. This approach bridges remote sensing analytics and geomorphological processes, facilitating large-scale environmental monitoring and sustainable erosion management. Understanding the effectiveness of engineering measures in mitigating surface erosion is crucial for sustainable land management. However, studies explicitly quantifying the combined effects of large-scale engineering measures and environmental factors remain limited. In this study, multisource remote sensing data were integrated with interpretable machine learning to quantify and analyze the regional influence of erosion control measures. We constructed a comprehensive indicator system encompassing spectral, textural, and topographic variables derived from high-resolution satellite imagery and DEM data. To address model transparency and enhance the interpretability of the results, we employed an interpretable machine learning framework capable of both accurate prediction and explicit attribution of feature importance. The results indicate that the implementation of engineering measures substantially reduces erosion intensity across the study area. Spatial heterogeneity in erosion mitigation effectiveness was closely associated with the distribution patterns of engineering measures and site-specific environmental conditions. Basins with a high proportion of check dams showed average elevation gains of up to 2.5 m compared with those without check dams, and terraces contributed to elevation increases of ~1.9 m in typical loess hilly regions. The interpretable machine learning model achieved $R^2 = 0.62$ at Basin 1 (average area ~100 km²) and $R^2 = 0.73$ at Basin 2 (~600 km²), demonstrating reliable predictive capability. The findings not only validate the role of engineering interventions in erosion mitigation but also provide a transparent analytical framework that connects remote sensing analytics with process-based geomorphological understanding. © 2025 by the authors.

Quantifying fire severity: a brief review and recommendations for improvement

Item Type Journal Article

Author G. Yang

Author D. Han

Author X. Di

Author L. Sun

Author Y. Weng

Abstract Introduction: Quantifying fire severity is an important aspect of studying the response mechanism of terrestrial ecosystems to wildfire, and it is of great significance to fire ecology. In this paper we comprehensively introduce and compare the classification and quantification methods for fire severity; we discuss the development and application status of various methods, and we elucidate their existing problems. Results: 1) According to features of the burned area, fire severity can be classified as light, moderate, and heavy. 2) Using composite burn index (CBI) to quantify and record the fire severity. 3) In quantifying fire severity with vegetation change, there are certain limitations and theoretical problems to be solved. 4) Remote sensing could very well be an important means of measuring fire severity in the future, but there are still many problems that need to be solved before the remote sensing index can become a global fire severity indicator. Discussion and Conclusion: Only by clarifying the relationship between fire behavior, fire severity, time related variables and the pre- and post-fire ecosystem can the existing models be perfected or new, better fire severity measurement models be proposed for broad applications. © 2021 The Author(s). Quantifying homeliness: Bridging the semantic gap in China's elderly care facility design

Item Type Journal Article

Author D. Zhou

Author J. Dai

Abstract In response to global aging, creating “homeliness”-oriented elderly care facilities has become a core goal to improve the elderly’s quality of life and emotional attachment to the environment. However, “homeliness” remains a subjective concept, lacking objective metrics to guide spatial design. This study introduces a novel methodology combining OneFormer-based image semantic segmentation and machine learning, to quantify the perceptual quality of spatial environments, and translate the findings into actionable design strategies for elderly care facilities. Through field surveys and interviews across 24 home care and 20 institutional care facilities in Xi'an, combined with a systematic literature review, we first established a quantifiable spatial assessment system based on elderly living patterns and emotional needs. Using OneFormer for spatial image semantic segmentation, we extracted and analyzed

environmental indicators from spatial imagery, identifying key qualitative and quantitative differences between the home care and institutional care settings. Multiple machine learning models, interpreted via SHAP values, were then applied to elucidate the relationships between spatial elements and perceived “homeliness.” Based on “homeliness” characteristics, the study proposes spatial reconstruction strategies (unit types, layout) and targeted design advice for residential spaces, communal activity spaces and corridors, to build elderly care environments that enhance the well-being of the elderly. © 2026 The Authors. Quantifying Inflammatory Response and Drug-Aided Resolution in an Atopic Dermatitis Model with Deep Learning

Item Type Journal Article

Author D.A. Greenfield

Author A. Feizpour

Author C.L. Evans

Abstract Noninvasive quantification of dermal diseases aids efficacy studies and paves the way for broader enrollment in clinical studies across varied demographics. Related to atopic dermatitis, accurate quantification of the onset and resolution of inflammatory flare ups in the skin remains challenging because the commonly used macroscale cues do not necessarily represent the underlying inflammation at the cellular level. Although atopic dermatitis affects over 10% of Americans, the genetic underpinnings and cellular-level phenomena causing the physical manifestation of the disease require more clarity. Current gold standards of quantification are often invasive, requiring biopsies followed by laboratory analysis. This represents a gap in our ability to diagnose and study skin inflammatory disease as well as develop improved topical therapeutic treatments. This need can be addressed through noninvasive imaging methods and the use of modern quantitative approaches to streamline the generation of relevant insights. This work reports the noninvasive image-based quantification of inflammation in an atopic dermatitis mouse model on the basis of cellular-level deep learning analysis of coherent anti-Stokes Raman scattering and stimulated Raman scattering imaging. This quantification method allows for timepoint-specific disease scores using morphological and physiological measurements. The outcomes we show set the stage for applying this workflow to future clinical studies. © 2023 The Authors

Quantifying Interdisciplinarity in Scientific Articles Using Deep Learning Toward a TRIZ-Based Framework for Cross-Disciplinary Innovation

Item Type Journal Article

Author N. Douard

Author A. Samet

Author G. Giakos

Author D. Cavallucci

Abstract Interdisciplinary research (IDR) is essential for addressing complex global challenges that surpass the capabilities of any single discipline. However, measuring interdisciplinarity remains challenging due to conceptual ambiguities and inconsistent methodologies. To overcome these challenges, we propose a deep learning approach that quantifies interdisciplinarity in scientific articles through semantic analysis of titles and abstracts. Utilizing the Semantic Scholar Open Research Corpus (S2ORC), we leveraged metadata field tags to categorize papers as either interdisciplinary or monodisciplinary, establishing the foundation for supervised learning in our model. Specifically, we preprocessed the textual data and employed a Text Convolutional Neural Network (Text CNN) architecture to identify semantic patterns indicative of interdisciplinarity. Our model achieved an F1 score of 0.82, surpassing baseline machine learning models. By directly analyzing semantic content and incorporating metadata for training, our method addresses the limitations of previous approaches that rely solely on bibliometric features such as citations and co-authorship. Furthermore, our large-scale analysis of 136 million abstracts revealed that approximately 25% of the literature within the specified disciplines is interdisciplinary. Additionally, we outline how our quantification method can be integrated into a TRIZ-based (Theory of Inventive Problem Solving) methodological framework for cross-disciplinary innovation, providing a foundation for systematic knowledge transfer and inventive problem solving across domains. Overall, this approach not only offers a scalable measurement of interdisciplinarity but also contributes to a framework for facilitating innovation through structured cross-domain knowledge integration. © 2025 by the authors.

Abstract Recent studies have suggested that irregular pulsation of intracranial aneurysm during the cardiac cycle may be potentially associated with aneurysm rupture risk. However, there is a lack of quantification method for irregular pulsations. This study aims to quantify irregular pulsations by the displacement and strain distribution of the intracranial aneurysm surface during the cardiac cycle using four-dimensional CT angiographic image data. Four-dimensional CT angiography was performed in 8 patients. The image data of a cardiac cycle was divided into approximately 20 phases, and irregular pulsations were detected in four intracranial aneurysms by visual observation, and then the displacement and strain of the intracranial aneurysm was quantified using coherent point drift and finite element method. The displacement and strain were compared between aneurysms with irregular and normal pulsations in two different ways (total and stepwise). The stepwise first principal strain was

significantly higher in aneurysms with irregular than normal pulsations (0.20 ± 0.01 vs 0.16 ± 0.02 , $p=0.033$). It was found that the irregular pulsations in intracranial aneurysms usually occur during the consecutive ascending or descending phase of volume changes during the cardiac cycle. In addition, no statistically significant difference was found in the aneurysm volume changes over the cardiac cycle between the two groups. Our method can successfully quantify the displacement and strain changes in the intracranial aneurysm during the cardiac cycle, which may be proven to be a useful tool to quantify intracranial aneurysm deformability and aid in aneurysm rupture risk assessment. © 2024 The Authors

Quantifying microstickies via a new agglomeration technique

Item Type Conference Paper

Author Y. Ben

Author M. Ricard

Author G. Dorris

Abstract Despite the recognized importance of microstickies to the various deposition problems experienced in pulping, papermaking and printing operations, there is still no consensus on a proper method to quantify them. One proposed method is to agglomerate them in a pulp sample by a long cold storage or by exposure to reduced pressure conditions followed by a classification step to isolate them from the pulp, as macrostickies. In this paper, we tested this approach but using a more effective agglomeration method to convert microstickies into macrostickies. Using model systems to validate the microstickies quantification method, we describe how a relatively short boiling treatment along with controlled mixing promotes and speeds up the agglomeration process.

Quantifying multi-dimensional services of water ecosystems and breakpoint-based spatial radiation of typical regulating services considering the hierarchical clustering-based classification

Item Type Journal Article

Author X. Guan

Author Y. Xu

Author Y. Meng

Author W. Xu

Author D. Yan

Abstract This study proposes a set of water ecosystem services (WES) research system, including classification, benefit quantification and spatial radiation effect, with the goal of promoting harmonious coexistence between humans and nature, as well as providing a theoretical foundation for optimizing water resources management. Hierarchical cluster analysis was applied to categorize WES taking in to account the four nature constraints of product nature, energy flow relationships, circularity, and human social utility. A multi-dimensional benefit quantification methodology system for WES was constructed by combining the emergy theory with multidisciplinary methods of ecology, economics, and sociology. Based on the theories of spatial autocorrelation and breaking point, we investigated the spatial radiation effects of typical services in the cyclic regulation category. The proposed methodology has been applied to Luoyang, China. The results show that the Resource Provisioning (RP) and Cultural Addition (CA) services change greatly over time, and drive the overall WES to increase and then decrease. The spatial and temporal distribution of water resources is uneven, with WES being slightly better in the southern region than the northern region. Additionally, spatial radiation effects of typical regulating services are most prominent in S County. This finding suggests the establishment of scientific and rational intra-basin or inter-basin water management systems to expand the beneficial impacts of water-rich areas on neighboring regions. © 2023 Elsevier Ltd

Author A.K. Singh

Author K.S. Reddy

Abstract Understanding the spatiotemporal teleconnections of rainfall in India with large-scale modes of climate variability is crucial for agricultural planning, water resource management, and climate adaptation. This study investigates the long-term teleconnections of monsoon rainfall with the Indian Ocean Dipole (IOD) and El Niño-Southern Oscillation (ENSO) across different Agro Climatic Zones (ACZs) of India from 1901 to 2022 using correlation, partial correlation and interpretable machine learning to quantify their impacts in different ACZs. Results revealed significant correlations and partial correlations between monsoon rainfall with the June-July-August-September (JJAS), October-November-December (OND), and annual (AN) mean values of ENSO indices, while the correlation with IOD was mostly non-significant. The January-February (JF) and March-April-May (MAM) mean values of both ENSO and IOD indices were poorly correlated with rainfall. The JJAS mean values of indices consistently showed the strongest correlations and partial correlations with monsoon rainfall across all ACZs. Comparing the periods 1903–1962 and 1963–2022 revealed evolving teleconnections, suggesting a weakening influence in the ACZs of western and central parts of India and a strengthening influence in the ACZs of southern, eastern, and northern parts of the country. We also identified key climate indices using the Boruta algorithm to train a random forest model and quantified their impacts on rainfall variability using accumulated local effect plots for each ACZ, which revealed that ENSO has a more dominant impact on rainfall than the IOD in most ACZs. This analysis provides insights into regional climate dynamics and will aid in improved planning and management of water resources. © The Author(s), under exclusive licence to Springer-Verlag GmbH Austria, part of Springer Nature 2025.

Quantifying riverbank failure risk in tidal river deltas: A hybrid physics-based and data-driven framework

Item Type Journal Article

Author L. Cong Chinh

Author N.T. Pham

Author T. Khac Thac

Abstract The complex, nonlinear synergy between three-dimensional hydrodynamics and transient geotechnical processes governs riverbank erosion in tidal river deltas. Traditional assessments often decouple these mechanisms, limiting predictive accuracy under combined extreme forcings. This study proposes a novel hybrid deterministic-stochastic framework that integrates in-situ observations, physics-based modelling, and machine learning to quantify riverbank instability. First, a 3D RANS hydrodynamic model (Delft3D) was one-way coupled with transient seepage and limit-equilibrium models (GeoStudio) to generate model-derived reference stability states. Using the Buckingham Pi theorem, the physical variables were reduced to two critical dimensionless groups representing hydrodynamic toe scour (driven by secondary flows) and geotechnical susceptibility (driven by rapid drawdown pore-pressure lag). To formulate a generalised predictive metric, a Monte Carlo simulation was executed to generate a diverse synthetic dataset, upon which Logistic Regression was applied to calibrate a novel Composite Erosion Index (IE). The index was calibrated on a synthetic dataset comprising 500 Monte Carlo scenarios, each labelled by the coupled deterministic models. The data-driven calibration achieved a classification accuracy of 96.7% with respect to these model-derived reference labels, quantifying the fidelity of the closed-form index to the physics-based simulations rather than field-predictive skill, and isolated a decision boundary ($IE \geq 1.0$) that normalises the disparate magnitudes of fluid shear and soil resistance. Application to the highly dynamic Vam Nao River in the Vietnamese Mekong Delta indicated that catastrophic mass failures are most likely to occur when severe secondary currents and rapid tidal drawdown coincide in space and time. The proposed index provides a scalable screening tool for assessing geomorphic hazards and supporting the design of Nature-based Solutions (NbS) for riverbank stabilisation in complex deltaic environments. The calibrated coefficients are site-specific, and independent validation against dated field-failure inventories remains a priority for future work. © 2026 The Authors.

QUANTIFYING ROBUSTNESS IN TALL (TIMBER) BUILDINGS: A CASE STUDY

Item Type Conference Paper

Author K. Voulpiotis

Abstract Robustness research has become popular, however very little is known on its explicit quantification. This paper summarises a quantification method previously published by the main author and proceeds in demonstrating its step-by-step application with a case study tall timber building. A hypothetical 15-storey timber building is designed for normal loads and four improved options are designed to account for abnormal loads in order to increase the building's robustness. A detailed, nonlinear dynamic Finite Element model is set up in Abaqus® to model three ground floor column removal scenarios, and a Random Forest classifier is set up to propagate uncertainties and efficiently calculate the probability of certain collapse classes occurring and the importance of each input parameter. The results show how design improvements at the whole building scale (e.g., strong floors) have a higher impact on robustness performance than just improving the strength and ductility of some selected connections, although these results are exclusive to the building studied. The whole procedure is put in context of the practicing engineer, with a suggestion for a calculation-free, purely

qualitative robustness framework. The case study reinforces the importance of a sound conceptual design for achieving robustness in tall timber buildings. © 13th World Conference on Timber Engineering, WCTE 2023. All rights reserved.

Abstract Linking meta-omics and biogeochemistry approaches in soils has remained challenging. This study evaluates the use of an internal RNA extraction standard and its potential for making quantitative estimates of a given microbial community size (biomass) in soil metatranscriptomics. We evaluate commonly used laboratory protocols for RNA processing, metatranscriptomic sequencing and quantitative reverse transcription polymerase chain reaction (qRT-PCR). Metatranscriptomic profiles from soil samples were generated using two library preparation protocols and prepared in triplicates. RNA extracted from pure cultures of *Saccharolobus solfataricus* was added to the samples as an internal nucleic acid extraction standard (NAEstd). RNA reads originating from NAEstd were identified with a 99.9% accuracy. A remarkable replication consistency between triplicates was seen (average Bray–Curtis dissimilarity 0.03 ± 0.02), in addition to a clear library preparation bias. Nevertheless, the between-sample pattern was not affected by library type. Estimates of 16S rRNA transcript abundance derived from qRT-PCR experiments, NAEstd and a previously published quantification method of metatranscriptomics (hereafter qMeTra) were compared with microbial biomass carbon (MBC) and nitrogen (MBN) extracts. The derived biomass estimates differed by orders of magnitude. While most estimates were significantly correlated with each other, no correlation was observed between NAEstd and MBC extracts. We discuss how simultaneous changes in community size and the soils nucleic acid retention strength might hamper accurate biomass estimation. Adding NAEstd has the potential to shed important light on nucleic acid retention in the substance matrix (e.g., soil) during extraction. © 2025 The Author(s). Quantifying technology-industry spillover effects based on patent citation network analysis of unmanned aerial vehicle (UAV)

Item Type Journal Article

Author D.H. Kim

Author B.K. Lee

Author S.Y. Sohn

Abstract Unmanned aerial vehicle (UAV) technologies have been fast developing over the past 20 years and are expected to generate extensive spillovers into other industry sectors. However, no previous studies have investigated such spillover effects. In this study, we propose the framework of two-mode network analysis to quantify the spillover effects of UAV technology into various industries using patent citation data of the United States Patent and Trademark Office. A two-mode matrix consists of rows corresponding to UAV technologies and columns corresponding to beneficiary industries, and the value depicts the spillover probability obtained using International

Patent Classification codes and the technology/industry concordance table. The out- and in-degree centralities of the spillover network are used to identify strong spillover-generating UAV technologies and strong spillover-receiving industries, respectively. We observed that the weapon industry received extensive spillover effects during the period 2005-2009. Based on Mann-Kendall tests, the spillover effects of UAV-related software technologies exhibited a consistently upward trend during both the last 10 and 20 years. The past significant trend of spillovers can help us to forecast future trends. The proposed quantification method can be readily applied to investigate other specific technology-industry spillover patterns. © 2016 Elsevier Inc.

Quantifying terrestrial carbon in the context of climate change: a review of common and novel technologies and methods

Item Type Journal Article**Author** S. Gameiro**Author** M.E. Ferreira**Author** L.F.C. Ruiz**Author** G.L. Galford**Author** M. Zeraatpisheh**Author** V.F. Nascimento**Author** R.G. Collevatti

Abstract Background: Understanding carbon dynamics in Earth's ecosystem is necessary for mitigating climate change. With recent advancements in technologies, it is important to understand both how carbon quantification in soil and vegetation is measured and how it can be improved. Therefore, this study conducted a bibliometric and bibliographic review of the most common carbon quantification methodologies. Results: Among the most widely used techniques, the Walkley-Black method and Elemental Analysis stand out for measuring below-ground carbon, while forest inventories are prominent for assessing above-ground carbon. Additionally, we found that the United States and China have the largest number of publications on this topic, with forest and agricultural areas being the most studied, followed by grasslands and mangroves. However, it should be noted that despite being indirect techniques, remote sensing, regression analysis, and machine learning have increasingly been used to generate geo-environmental carbon models for various areas. Landsat satellite images are the most widely used in remote sensing, followed by LiDAR digital models. Conclusions: These results demonstrate that while new technologies do yet not replace analytical techniques, they are valuable allies working in conjunction with the current carbon quantification process. © The Author(s) 2025.

Quantifying the effect of vortex generator installation on wind power production: An academia-industry case study

Item Type Journal Article

Author H. Hwangbo

Author Y. Ding

Author O. Eisele

Author G. Weinzierl

Author U. Lang

Author G. Pechlivanoglou

Abstract This paper presents an academia-industry joint study concerning effective methods to estimate and quantify the effect of vortex generator installation on wind power production. This problem has presented a challenge to the wind industry, because (a) vortex generator installation may lead to a moderate 1–5% extra power production, but this level of improvement is difficult to be accurately detected; and (b) it is equally difficult to validate the estimated effect of vortex generator installation because a controlled experiment is practically impossible to conduct to provide a credible baseline. An academic institute and a wind technology company team up to tackle this challenge. The two teams develop their own version of quantification methods, which are profoundly different. The academic method uses 10-min data and makes use of both power and environmental data, whereas the company method uses high-frequency data via primarily a direct power comparison approach that relies less on the environmental data. When applying the respective methods to two inland wind farms, each of which presents four pairs of turbines, the quantification results from the two methods are surprisingly consistent. We believe the consistent outcome presents a strong case of cross validation, testifying to the respective method's capability and credibility. © 2017 Elsevier Ltd

Quantifying the effects of urban fabric and vegetation combination pattern to mitigate particle pollution in near-road areas using machine learning

Item Type Journal Article**Author** X. Liu**Author** X.-Q. Shi**Author** Z.-R. Peng**Author** H.-D. He

Abstract There are many intertwined factors such as urban fabric, vegetation combination, and meteorological conditions that influence the spatial distribution of fine particles (PM_{2.5}, aerodynamic diameter less than 2.5 μm) in near-road urban areas, and it is difficult yet important to disentangle them. Identifying the relative importance of those factors could facilitate designing urban fabric and roadside vegetation combination patterns to mitigate the negative impacts of particles. This study first proposes an effective and reliable integrated method of the ENVI-met microclimate model and interpretable machine learning to quantify the multifactorial effects. Data from ENVI-met models with different built environments and meteorological conditions are used to train and test the machine learning (ML) models. All ML models show high accuracy in predicting PM_{2.5} concentrations with R² high than 0.87. Results indicate that height level and study area are the two most important features, explaining 22.8% and 20.4% of the variation in PM_{2.5} concentration, respectively. The feature pairwise interactions account for 45.8% of ambient particle concentrations. The combination of trees and hedges in urban fabrics with longer building length than width could mitigate PM_{2.5} concentrations in residential areas. The integrated methods in this study could be extrapolated to future research to perform source identification analysis. © 2023 Elsevier Ltd

Quantifying the Impact of Urban Air Quality on Individual Well-being: A Multimodal Approach for Stress Classification

Item Type Conference Paper

Author K.I. Tusó

Author E.N. Capuchino

Author R.L. Nierva

Author N. Orillaza

Author M. Rosales

Author J.R. Hizon

Abstract Urban air pollution contributes to respiratory diseases, cardiovascular conditions, and mental stress. This study explores the relationship between individual exposure to air pollution and well-being, by integrating quantitative and qualitative methods, focusing on psychological stress levels through multimodal

data collection. It integrates real-time physiological measurements (e.g., heart rate), environmental sensors (e.g., PM2.5 sensor), and self-reported psychological stress to develop a classification framework for stress episodes based on exposure patterns. The study employs Geographic Information Systems (GIS), Pearson's R correlation, and machine learning techniques such as Random Forest and k-Nearest Neighbors (kNN) to analyze spatial-temporal exposure data and assess the correlations between urban air quality and individual well-being. Stationary air quality monitoring nodes provide confidence in the measured data through the wearable air quality monitor. Findings show that environmental and physiological data can classify momentary psychological stress, showing 98.56% accuracy with Random Forest model, which can be built on top of emotion analysis for expansion of well-being classification. This study fills research gaps by combining real-time data collection and machine learning to quantify the complex relationship between urban air quality and individual well-being. © 2025 IEEE.

Quantifying the partial volume effect in PET using Benford's Law

Item Type Journal Article

Author K. Wells

Author J. Chiverton

Author M. Partridge

Author M. Barry

Author H. Kadhem

Author B. Ott

Abstract Partial Volume (PV) correction techniques in PET or SPECT represents a key step in image quantification methods. The PV effect arises because of the blurring induced by the imaging system's Point Spread Function (PSF), producing intra-voxel mixing of the signals arising from different functional tissue classes. Quantification of this effect is often required to recover the mixing components within a group of voxels, from whence the true tissue concentration in a given volume or region can be estimated. In this work we consider a probabilistic methodology that uses a phenomenological distribution known as Benford's Law to quantify the partial volume effect. We establish for the first time, that the probability distribution of voxels subjected to the PV effect in discrete volumetric data can be well described by Benford's Law. The probabilistic framework devised here can be applied generically across different imaging modalities including PET and SPECT. Results from simulated data are presented, along with a PET phantom study utilizing registered processed CT data as ground truth, to determine the quality of the resulting probabilistic voxel classification scheme. For a water filled hot insert using a 5:1 insert:background activity concentration, we find an overall voxel RMS error of 3% (compared to ground truth) in the estimated voxel mixing vectors. This error rises to 8% for a cold air-filled insert in a warm background. © 2007 IEEE.

Quantifying the spatial quality of urban streets with open street view images: A case study of the main urban area of Fuzhou

Item Type Journal Article

Author Q. Rui

Author H. Cheng

Abstract With the advancement of global urbanization, urban streetscapes have become a critical part of urban public spaces. As one of the important ways to enhance the living environment, relevant government departments have accelerated the construction of urban streetscapes; however, certain issues, such as emphasis on surface and light protection, still persist. The visual effects of street landscapes hardly meet people's daily and spiritual needs. Therefore, assessing the quality of urban streetscapes has scientific and practical significance for improving urban planning and construction and creating a new intelligent and green city. In this study, the spatial distribution of vehicle interference index, spatial feasibility index, road area index, green visual index, sky visibility index, spatial enclosure index, color richness index, and visual entropy evaluation indices were drawn from the framework of combining deep learning and machine learning to quantify the spatial quality of urban streets by integrating a large number of streetscape images. The spatial quality of street landscape was evaluated according to the ELO scoring mechanism and random forest method, taking the main urban area of Fuzhou City as an example. The results showed that the overall street landscape quality of Fuzhou City was high, and the spatial distribution showed a pattern of concentrated high values in the center and dispersed high values in the periphery. Therefore, based on quantifying the spatial quality of urban streets, strategies, such as the pavement layout of pedestrian and vehicular paths, control of the continuity and permeability of visual landscape elements, and plant color matching, should be regulated. The method proposed in this study can provide novel insights for urban builders to improve the construction of cities. © 2023

Quantifying trends accurately despite classifier error and class imbalance

Item Type Conference Paper

Author G. Forman

Abstract This paper promotes a new task for supervised machine learning research: quantification - the pursuit of learning methods for accurately estimating the class distribution of a test set, with no concern for predictions on individual cases. A variant for cost quantification addresses the need to total up costs according to categories predicted by imperfect classifiers. These tasks cover a large and important family of applications that measure trends over time. The paper establishes a research methodology, and uses it to evaluate several proposed methods that involve selecting the classification threshold in a way that would spoil the accuracy of individual classifications. In empirical tests, Median Sweep methods show outstanding ability to estimate the class distribution, despite wide disparity in testing and training conditions. The paper addresses shifting class priors and costs, but not concept drift in general. Copyright 2006 ACM.

Quantifying uncertainty in foraminifera classification: How deep learning methods compare to human experts

Item Type Journal Article

Author I. Martinsen

Author S.A. Sørensen

Author S. Ortega

Author F. Godtliebsen

Author M. Tejedor

Author E. Myrvoll-Nilsen

Abstract Foraminifera are shell-bearing microorganisms that are commonly found in marine deposits on the seabed. They are important indicators in many analyses, are used in climate change research, monitoring marine environments, evolutionary studies, and are also frequently used in the oil and gas industry. Although some research has focused on automating the classification of foraminifera images, few have addressed the uncertainty in these classifications. Although foraminifera classification is not a safety-critical task, estimating uncertainty is crucial to avoid misclassifications that could overlook rare and ecologically significant species that are informative indicators of the environment in which they lived. Uncertainty estimation in deep learning has gained significant attention and many methods have been developed. However, evaluating the performance of these methods in practical settings remains a challenge. To create a benchmark for uncertainty estimation in the classification of foraminifera, we administered a multiple choice questionnaire containing classification tasks to four senior geologists. By analyzing their responses, we generated human-derived uncertainty estimates for a test set of 260 images of foraminifera and sediment grains. These uncertainty estimates served as a baseline for comparison when training neural networks in classification. We then trained multiple deep neural networks using a range of uncertainty quantification methods to classify and state the uncertainty about the classifications. The results of the deep learning

uncertainty quantification methods were then analyzed and compared with the human benchmark, to see how the methods performed individually and how the methods aligned with humans. Our results show that human-level performance can be achieved with deep learning and that test-time data augmentation and ensembling can help improve both uncertainty estimation and classification performance. Our results also show that human uncertainty estimates are helpful indicators for detecting classification errors and that deep learning-based uncertainty estimates can improve calibration and classification accuracy. © 2025 The Authors

Author Y.-C. Shen

Author Y. Kono

Abstract In numerous applications of land-use/land-cover (LULC) classification, the classification rules are determined using a set of training data; thus, the results are inherently affected by uncertainty in the selection of those data. Few studies have assessed the accuracy of LULC classification with this consideration. In this article, we provide a general expression of various measures of classification accuracy with regard to the sample data set for classifier training and the sample data set for the evaluation of the classification results. We conducted stochastic simulations for LULC classification of a two-feature two-class case and a three-feature four-class case to show the uncertainties in the training sample and reference sample confusion matrices. A bootstrap simulation approach for establishing the 95% confidence interval of the classifier global accuracy was proposed and validated through rigorous stochastic simulation. Moreover, theoretical relationships among the producer accuracy, user accuracy, and overall accuracy were derived. The results demonstrate that the sample size of class-specific training data and the a priori probabilities of individual LULC classes must be jointly considered to ensure the correct determination of LULC classification accuracy. © Copyright © 2021 Cheng, Ling, Lin, Liu, Shen and Kono.

Quantifying uncertainty in machine learning for nuclear binding energy

Item Type Journal Article

Author M. Huang

Author K.A. Wendt

Author N.F. Schunck

Author E.M. Holmbeck

Abstract Techniques from artificial intelligence and machine learning are increasingly employed in nuclear theory; however, the uncertainties that arise from the complex parameter manifold encoded by the neural networks are often overlooked. Epistemic uncertainties arising from training the same network multiple times for an ensemble of initial weight sets offer a first insight into the confidence of machine learning predictions, but they often come with a high computational cost. Instead, we apply a single-model uncertainty quantification method called Δ -UQ that gives epistemic uncertainties with one-time training. We demonstrate our approach on a two-feature model of nuclear binding energies per nucleon with proton and neutron number pairs as inputs. We show that Δ -UQ can produce reliable and self-consistent epistemic uncertainty estimates and can be used to assess the degree of confidence in predictions made with deep neural networks. © 2025 American Physical Society

Abstract Introduction: Transthyretin (ATTR) amyloidosis is responsible for the majority of cardiac amyloidosis (CA) cases and can be reliably diagnosed with bone scintigraphy and the visual Perugini score. We aimed to implement a quantification method of cardiac amyloid deposits in patients with suspected cardiac amyloidosis and to compare performance to visual scoring. Methods and materials: 136 patients received ^{99m}Tc-DPD-bone scintigraphy including SPECT/CT of the thorax in case of suspicion of cardiac amyloidosis. Imaging phantom studies were performed to determine the scaling factor for standardized uptake value (SUV) quantification from SPECT/CT. Myocardial tracer uptake was quantified in a whole heart volume of interest. Results: Forty-five patients were diagnosed with CA. A strong relationship between cardiac SUVmax and Perugini score was found (Spearman r 0.75, $p < 0.0001$). Additionally, tracer uptake in bone decreased with increasing cardiac SUVmax and Perugini score ($p < 0.0001$). ROC analysis revealed good performance of the SUVmax for the detection of ATTR-CA with AUC of 0.96 ± 0.02 ($p < 0.0001$) with sensitivity 98.7% and specificity 87.2%. Conclusion: We demonstrate an accessible and accurate quantitative SPECT approach in CA. Quantitative assessment of the cardiac tracer uptake may improve diagnostic accuracy and risk classification. This method may enable monitoring and assessment of therapy response in patients with ATTR amyloidosis. © 2022, The Author(s).

Abstract A multi-parameter quantification method was implemented to quantify retinal vascular injuries in microscopic images of clinically relevant eye diseases. This method was applied to wholemount retinal trypsin digest images of diabetic Akita/+, and bcl-2 knocked out mice models. Five unique features of retinal vasculature were extracted to monitor early structural changes and retinopathy, as well as quantifying the disease progression. Our approach was validated through simulations of retinal images. Results showed fewer number of cells ($P = 5.1205e-05$), greater population ratios of endothelial cells to pericytes (PCs) ($P = 5.1772e-04$; an indicator of PC loss), higher fractal dimension ($P = 8.2202e-05$), smaller vessel coverage ($P = 1.4214e-05$), and greater number of acellular capillaries ($P = 7.0414e-04$) for diabetic retina as

compared to normal retina. Quantification using the present method would be helpful in evaluating physiological and pathological retinopathy in a high-throughput and reproducible manner. © 2016 Journal of Medical Signals & Sensors.

Abstract Objective: Recent epidemiologic studies worldwide have documented a rise in prevalence rates for autism spectrum disorders (ASD). Broadening of diagnostic criteria for ASD may be a major contributor to the rise in prevalence, particularly if superimposed on an underlying continuous distribution of autistic traits. This study sought to determine the nature of the population distribution of autistic traits using a quantitative trait measure in a large national population sample of children. Method: The Japanese version of the Social Responsiveness Scale (SRS) was completed by parents on a nationally representative sample of 22 529 children, age 6-15. Results: Social Responsiveness Scale scores exhibited a skewed normal distribution in the Japanese population with a single-factor structure and no significant relation to IQ within the normal intellectual range. There was no evidence of a natural 'cutoff' that would differentiate populations of categorically affected children from unaffected children. Conclusion: This study provides evidence of the continuous nature of autistic symptoms measured by the SRS, a validated quantitative trait measure. The findings reveal how paradigms for diagnosis that rest on arbitrarily imposed categorical cutoffs can result in substantial variation in prevalence estimation, especially when measurements used for case assignment are not standardized for a given population. © 2012 John Wiley & Sons A/S. Quantitative classification and threshold determination of rock blasting damage based on blasting crater tests and numerical simulation

Item Type Journal Article

Author M. Zhao

Author Á. Prado

Author N. Jiang

Author X. Meng

Author Y. Yang

Abstract The RHT constitutive model has been widely applied in numerical simulations of rock blasting. However, a clear quantitative relationship between its damage variable D and macroscopic fragmentation degree is still lacking. In this study, single-hole blasting experiments were combined with LS-DYNA simulations to investigate crater morphology, fragment size distribution, and damage evolution. A damage quantification method based on damaged volume ratio was proposed, establishing a direct quantitative correlation between the RHT damage variable D and fragmentation degree. Based on this relationship, blast-induced damage is classified into four levels: undamaged/slight damage ($0 \leq D \leq 0.3$), moderate damage ($0.3 \leq D \leq 0.8$), severe damage ($0.8 \leq D \leq 0.9$), and crushed damage ($0.9 \leq D \leq 1$). The proposed damage–fragmentation correlation provides a quantitative reference for interpreting numerical damage fields and offers practical guidance for improving blasting damage prediction and fragmentation control in numerical simulations. Quantitative color profiling of digital images with earth mover's distance using the R package colordistance

Item Type Journal Article

Author H.I. Weller

Author M.W. Westneat

Abstract Biological color may be adaptive or incidental, seasonal or permanent, species- or population-specific, or modified for breeding, defense or camouflage. Although color is a hugely informative aspect of biology, quantitative color comparisons are notoriously difficult. Color comparison is limited by categorization methods, with available tools requiring either subjective classifications, or expensive equipment, software, and expertise. We present an R package for processing images of organisms (or other objects) in order to quantify color profiles, gather color trait data, and compare color palettes on the basis of color similarity and amount. The package treats image pixels as 3D coordinates in a “color space,” producing a multidimensional

color histogram for each image. Pairwise distances between histograms are computed using earth mover's distance, a technique borrowed from computer vision, that compares histograms using transportation costs. Users choose a color space, parameters for generating color histograms, and a pairwise comparison method to produce a color distance matrix for a set of images. The package is intended as a more rigorous alternative to subjective, manual digital image analyses, not as a replacement for more advanced techniques that rely on detailed spectrophotometry methods unavailable to many users. Here, we outline the basic functions of colordistance, provide guidelines for the available color spaces and quantification methods, and compare this toolkit with other available methods. The tools presented for quantitative color analysis may be applied to a broad range of questions in biology and other disciplines. © 2019 Weller and Westneat.

Abstract Inflammatory bowel disease (IBD) is a condition of unknown etiology. Eosinophilia is sometimes prominent in pathological specimens of the small and large intestines of patients with IBD, but no consensus exists on the clinical significance of eosinophils in IBD. Eosinophil quantification methods include manual counting by pathologists and software analysis. In this study, we aimed to establish a quantitative technique for tissue eosinophils in small and large intestinal pathological specimens of IBD using artificial intelligence-based software and confirm its pathological validity. Small and large intestine specimens were collected from 40 patients. Hematoxylin and eosin-stained slides were prepared and scanned using WSI. In the eosinophil-rich field of view for the 39 cases, the eosinophil counts of the two pathologists and the software were performed. The software was trained in advance using the remnant case. Significant positive correlations were found between the eosinophil counts of the two pathologists' average and the software (Spearman's rank correlation coefficient = 0.919, $P = 1.62 \times 10^{-16}$) and of the two pathologists (Spearman's rank correlation coefficient = 0.767, $P = 0.0000000122$). Moreover, the average eosinophil counts of the two pathologists were predicted using the eosinophil count software. These results will enable future investigation of the clinicopathological significance (differential diagnosis, treatment response, and prognosis) of the total tissue eosinophil count in IBD, as well as reproducible assessment of disease activity in terms of eosinophils. © 2026 The Authors.

Quantitative performance evaluation algorithms for pavement distress segmentation

Item Type Journal Article**Author** V. Kaul**Author** Y. Tsai**Author** R.M. Mersereau

Abstract Algorithms for pavement distress image segmentation are crucial to developing an automatic pavement distress detection and classification system. Many algorithms for pavement distress segmentation have been developed in the past decade; however, the lack of good methods to evaluate their performance quantitatively hinders the focused development of better segmentation algorithms. In this paper, a novel method is developed to quantitatively evaluate the performance of different pavement distress segmentation algorithms. This method uses the buffered Hausdorff distance to estimate the deviation of the cracks in the automatically segmented image from the ground truth cracks. The proposed method captures the local effectiveness of segmentation methods around the crack region without compromising its robustness to isolated pixel deviations caused by noise. Besides real pavement images, synthetic images simulating extreme pavement distress conditions are used to evaluate the capability of the proposed method and show its merits. The proposed method outperforms four other possible quantification methods and demonstrates its superior capability in providing a better score separation to distinguish the performance of different segmentation algorithms.

Quantitative relationships between soil landscape index and classification grain

Item Type Journal Article

Author Y. Pan

Author X. Lu

Author D. Yu

Author J. Huang

Author X. Sun

Author Z. Xu

Abstract Purpose: Understanding space grain impact on soil landscape patterns is helpful to discover specific spatial heterogeneity of soil landscape. The objectives of this study were to reveal the effect of soil classification grain on soil landscape indices and establish a quantitative characterization function between soil landscape index and soil classification grain then we can reveal the sensitivity of soil landscape indices to soil classification grain and the significance of the function with respect to practical applications. Materials and methods: A soil and land use vector map of Dongxiang County was made at a scale of 1:50,000. The vector map units were classified into five hierarchies of soil classification grain, such as soil great group (G1), subgroup (G2), family (G3), species (G4), and species + land use (G5). Using Fragstats 4.2 software, 40 soil landscape indices of the five soil classification grains were calculated from the vector map and its derived raster maps, at different grain sizes ranging from 10 m × 10 m to 6 km × 6 km. A numerically investigated method was developed to quantify and analyze values of the different soil classification grains, quantitative relationships, and sensitivities of soil landscape indices to soil classification grains. Results and discussion: The effects of soil classification grain varied according to different soil landscape indices. The quantitative values of G1-G5 soil classification grains were quantified to be 0.7 km × 0.7 km, 0.5 km × 0.5 km, 0.2 km × 0.2 km, 0.15 km × 0.15 km, and 0.06 km × 0.06 km, respectively. The quantitative relationships of the abovementioned 28 landscape indices to soil classification grain were described by linear, logarithmic, reciprocal, quadratic, and power function with different sensitivities. The 13 landscape indices and their functions of the quantitative relationships to soil classification grain, which exhibited high sensitivity coefficients (PEAR > 0.90), should be adopted as a new approach in the future to quantitatively assess and forecast the spatial heterogeneity of soil landscape. Conclusions: The soil classification grain strongly affects the spatial heterogeneity of the soil landscape. The quantification method of soil classification

grains and the quantitative expression functions between soil landscape indices and the classification grain developed in this study could potentially provide a basic tool to quantitatively assess and forecast the spatial heterogeneity of soil landscapes. Among them, the landscape indices with high sensitivity to soil classification grains should be preferentially adopted within the new approach. © 2018, Springer-Verlag GmbH Germany, part of Springer Nature.

Author J. Xue

Author B. Yu

Abstract Traditional fingerprint identification primarily relies on the number of matching minutiae between the questioned and reference prints, where identity is determined by whether the match count exceeds a fixed threshold. However, this “minimum matching pair threshold method” lacks statistical validation. This study establishes a large-scale fingerprint data analysis framework based on artificial intelligence and machine learning to quantify the discriminative value of fingerprint minutiae. A YOLOv12 hybrid model is designed for high-precision minutiae detection. Using 619,338 fingerprints from four pattern classes, the occurrence frequencies of six types of minutiae are statistically analyzed, providing the foundation for quantitative modeling. A minutiae matching method is further proposed to perform large-scale matching according to specified minutia types and quantities. The approach integrates three modules: positional matching, local ridge-flow similarity comparison, and image similarity evaluation. 772 million pairs of non-mated fingerprints are analyzed to empirically refine traditional identification methods and quantify feature-level discriminative value. Results indicate that fingerprint matching stability depends not only on minutiae count but also on fingerprint pattern and minutia types. Building upon Shannon's information theory, a quantitative model for evaluating minutiae discriminative value is established based on feature frequency and matching performance. After residual correction, the model achieves a coefficient of determination (R^2) of 0.958, demonstrating high explanatory power and robustness. © 2026 American Academy of Forensic Sciences.

Quantitative wavelength analysis and image classification for intraoperative cancer diagnosis with hyperspectral imaging

Item Type Conference Paper**Author** G. Lu**Author** X. Qin**Author** D. Wang**Author** Z.G. Chen**Author** B. Fei**Editor** Webster R.J.**Editor** Yaniv Z.R.

Abstract Complete surgical removal of tumor tissue is essential for postoperative prognosis after surgery. Intraoperative tumor imaging and visualization are an important step in aiding surgeons to evaluate and resect tumor tissue in real time, thus enabling more complete resection of diseased tissue and better conservation of healthy tissue. As an emerging modality, hyperspectral imaging (HSI) holds great potential for comprehensive and objective intraoperative cancer assessment. In this paper, we explored the possibility of intraoperative tumor detection and visualization during surgery using HSI in the wavelength range of 450 nm - 900 nm in an animal experiment. We proposed a new algorithm for glare removal and cancer detection on surgical hyperspectral images, and detected the tumor margins in five mice with an average sensitivity and specificity of 94.4% and 98.3%, respectively. The hyperspectral imaging and quantification method have the potential to provide an innovative tool for image-guided surgery. © 2015 SPIE.

Quantitatively understanding the ozone formation characteristics in areas with heavy precursor emission through machine learning simulations

Item Type Journal Article**Author** Q. Wang**Author** S. Yao**Author** C. Zhu**Author** S. Huang**Author** X. Ou**Author** J. Zhao**Author** S. Zhang**Author** W. Li**Author** J. Chen

Abstract The understanding of ozone (O₃) formation processes in polluted industrial areas remains limited. A machine learning (ML) approach combining random forest (RF) and artificial neural network (ANN) algorithms was proposed, showing a strong predictive performance of 0.940 in R². Analysis of variable importance suggests that NO₂ concentration, temperature (T), and relative humidity (RH) are the most important variables. Focusing on prevalent conditions, we established a quantified function for predicting O₃ concentration based on these important variables, which demonstrates a robust predictive capability. The results suggesting that the influence of NO₂ concentration on O₃ formation is primarily controlled near linearly by T and quadratically by RH. These results improve the understanding of O₃ formation in those NO_x-sensitive and VOC-oversaturated areas, thereby providing further support for identifying high O₃ concentration periods and important influence variables, which help to mitigate the increase in O₃ concentration in similar areas. Additionally,

the RF-ANN model provided a deep understanding of O₃ formation characteristics, while the quantification method with controlled variables demonstrated their effectiveness and timeliness in supporting local O₃ concentration control strategies.

Quantum Computing and Quality Quantifiers Shaping the Future of Intelligent Systems

Item Type Conference Paper

Author D. Bhanu

Author M. Grover

Author M. Preetha

Author A. Mishra

Author S. Varalakshmi

Author V. Marathe

Abstract Quantum computing and quality quantifiers promote advanced computing. Their utilization will develop future smart systems. Quantum-Enhanced Quality Quantification (Q2) is introduced in this paper. Q2 combines quantum computing's built-in capabilities and quality quantification methodologies to

assess and enhance smart systems' performance, reliability, and morality. The proposed Q2 technique uses the quantum-enhanced quality integration (QEIQ), quality quantification (QQA), and quantum error correction (QEC) algorithms. Quantum error correction (QEC) uses stabilizer codes and syndromes to rectify quantum computing errors without affecting the quantum state. The Quality Quantification Algorithm rates system performance based on dependability, moral conformity, correctness, speed, and error rate. The QEIQ method uses new discoveries in quality measurement and error-corrected quantum data to make sure that smart systems offer solutions that are both technically correct and morally right. Six quantum computing methods were compared against Q2 to determine its performance: Quantum quantum, supreme accorrectiondes for quantum computing, quantum machine learning algorithms, quantum annealing, quality quantifiers for ethical AI, and quantum simulations in material science. Speed, accuracy, error rate, development, reliability, and morality determined success. The data reveal that Q2 outperforms traditional techniques in every manner. Precision, working speed, mistake rates, scalability, reliability, and morality improve. These findings demonstrate that Q2 can transform intelligent systems by improving technology and ensuring ethical behavior. © 2024 IEEE.

Quantum-Inspired Neural Stem Cell Optimization for histopathological breast cancer detection: A clinically-informed approach

Item Type Journal Article

Author A. Kumar

Author F. Ahmad

Author B. Alam

Abstract Breast cancer remains a leading cause of cancer-related morbidity among women worldwide, where early and reliable diagnosis is critical for improving clinical outcomes. This study proposes a hybrid classification framework integrating DenseNet201 for hierarchical feature extraction, a Quantum-Inspired Neural Stem Cell Optimization (QNSCO) algorithm for feature selection, and a Support Vector Machine (SVM) for final classification. The QNSCO algorithm reformulates classical stem cell optimization within a probabilistic amplitude-based representation to enhance exploration–exploitation balance in high-dimensional feature spaces. The framework was evaluated on the BreakHis histopathological dataset across four magnification levels (40×, 100×, 200×, and 400×) under binary and multi-class settings using patient-wise stratified validation and repeated cross-validation protocols. The proposed DenseNet201–QNSCO–SVM model achieved classification accuracies of 99.88% (binary) and 99.01% (multi-class), while maintaining strict fold-level isolation to prevent information leakage. External validation under zero-shot and few-shot transfer settings further demonstrated stable generalization under magnification shifts and class prevalence variations. These results indicate that the proposed framework provides a reproducible and computationally structured optimization approach for histopathological image analysis, with potential applicability in computer-aided diagnostic research. QuaPy: A Python-Based Framework for Quantification

Item Type Conference Paper

Author A. Moreo

Author A. Esuli

Author F. Sebastiani

Abstract QuaPy is an open-source framework for performing quantification (a.k.a. supervised prevalence estimation), written in Python. Quantification is the task of training quantifiers via supervised learning, where a quantifier is a predictor that estimates the relative frequencies (a.k.a. prevalence values) of the classes of interest in a sample of unlabelled data. While quantification can be trivially performed by applying a standard classifier to each unlabelled data item and counting how many data items have been assigned to each class, it has been shown that this "classify and count" method is outperformed by methods specifically designed for quantification. QuaPy provides implementations of a number of baseline methods and advanced quantification methods, of routines for quantification-oriented model selection, of several broadly accepted evaluation measures, and of robust evaluation protocols routinely used in the field. QuaPy also makes available datasets commonly used for testing quantifiers, and offers visualization tools for facilitating the analysis and interpretation of the results. The software is open-source and publicly available under a BSD-3 licence via <https://github.com/HLT-ISTI/QuaPy>, and can be installed via pip (<https://pypi.org/project/QuaPy/>). © 2021 ACM.

Quasar and galaxy classification in Gaia data release 2

Item Type Journal Article

Author C.A.L. Bailer-Jones

Author M. Fouesneau

Author R. Andrae

Abstract We construct a supervised classifier based on Gaussian Mixture Models to probabilistically classify objects in Gaia data release 2 (GDR2) using only photometric and astrometric data in that release. The model is trained empirically to classify objects into three classes - star, quasar, galaxy - for $G \geq 14.5$ mag down to the Gaia magnitude limit of $G = 21.0$ mag. Galaxies and quasars are identified for the training set by a cross-match to objects with spectroscopic classifications from the Sloan Digital Sky Survey. Stars are defined directly from GDR2. When allowing for the expectation that quasars are 500 times rarer than stars, and galaxies 7500 times rarer than stars (the class imbalance problem), samples classified with a threshold probability of 0.5 are predicted to have purities of 0.43 for quasars and 0.28 for galaxies, and completenesses of 0.58 and 0.72, respectively. The purities can be increased up to 0.60 by adopting a higher threshold. Not accounting for this expected low frequency of extragalactic objects (the class prior) would give both erroneously optimistic performance predictions and severely impure samples. Applying our model

to all 1.20 billion objects in GDR2 with the required features, we classify 2.3 million objects as quasars and 0.37 million objects as galaxies (with individual probabilities above 0.5). The small number of galaxies is due to the strong bias of the satellite detection algorithm and on-ground data selection against extended objects. We infer the true number of quasars and galaxies - as these classes are defined by our training set - to be 690 000 and 110 000, respectively (± 50 per cent). The aim of this work is to see how well extragalactic objects can be classified using only GDR2 data. Better classifications should be possible with the low resolution spectroscopy (BP/RP) planned for GDR3. © 2019 The Author(s)

RACENet: Real-time Adaptive Class-aware Early-exit Networks for Edge Devices

Item Type Conference Paper

Author M. Ayyat

Author M. Osman

Author T. Nadeem

Abstract As the integration of edge and IoT devices continues to surge, the need for streamlined machine learning solutions, notably Deep Neural Networks (DNNs), becomes paramount. However, the inherent computational demands and significant memory requirements of DNNs present hurdles for seamless edge integration. Early-Exit Networks (EENs) have emerged as a solution by adding early exits to DNNs, allowing for early inference and facilitating dynamic deployment on devices with varying capabilities. Despite their advantages, current EEN models uniformly handle samples from all classes, which is suboptimal in many edge scenarios where different classes require varying processing speeds and response times. Our research introduces RACENet, a novel architecture with adaptive early-exit capabilities that adjusts class prioritization in real-time. This flexibility enables RACENet to respond to evolving class priorities during runtime. Extensive evaluations on vision tasks, and network intrusion detection demonstrate that RACENet maintains accuracy while dynamically managing class priorities and accelerating inference for high-priority classes, all without adding additional computational burdens on constrained edge devices. © 2025 IEEE.

Radio Galaxy Zoo: using semi-supervised learning to leverage large unlabelled data sets for radio galaxy classification under data set shift

Item Type Journal Article

Author H. Tang

Abstract In this work, we examine the classification accuracy and robustness of a state-of-the-art semi-supervised learning (SSL) algorithm applied to the morphological classification of radio galaxies. We test if SSL with fewer labels can achieve test accuracies comparable to the supervised state of the art and whether this holds when incorporating previously unseen data. We find that for the radio galaxy classification problem considered, SSL provides additional regularization and outperforms the baseline test accuracy. However, in contrast to model performance metrics reported on computer science benchmarking data sets, we find that improvement is limited to a narrow range of label volumes, with performance falling off rapidly at low label volumes. Additionally, we show that SSL does not improve model calibration, regardless of whether classification is improved. Moreover, we find that when different underlying catalogues drawn from the same radio survey are used to provide the labelled and unlabelled data sets required for SSL, a significant drop in classification performance is observed, highlighting the difficulty of applying SSL techniques under data set shift. We show that a class-imbalanced unlabelled data pool negatively affects performance through prior probability shift, which we suggest may explain this performance drop, and that using the FrCrossed D sign $\odot$ chet distance between labelled and unlabelled data sets as a measure of data set shift can provide a prediction of model performance, but that for typical radio galaxy data sets with labelled sample volumes of $O(10^3)$, the sample variance associated with this technique is high and the technique is in general not sufficiently robust to replace a train-test cycle.

Random Balance ensembles for multiclass imbalance learning

Item Type Journal Article

Author J.J. Rodríguez

Author J.-F. Díez-Pastor

Author Á. Arnaiz-González

Author L.I. Kuncheva

Abstract Random Balance strategy (RandBal) has been recently proposed for constructing classifier ensembles for imbalanced, two-class data sets. In RandBal, each base classifier is trained with a sample of the data with a random class prevalence, independent of the a priori distribution. Hence, for each sample, one of the classes will be undersampled while the other will be oversampled. RandBal can be applied on its own or can be combined with any other ensemble method. One particularly successful variant is RandBalBoost which integrates Random Balance and boosting. Encouraged by the success of RandBal, this work proposes two approaches which extend RandBal to multiclass imbalance problems. Multiclass imbalance implies that at least two classes have substantially different proportion of instances. In the first approach proposed here, termed Multiple Random Balance (MultiRandBal), we deal with all classes simultaneously. The training data for each base classifier are sampled with random class proportions. The second approach we propose decomposes the multiclass problem into two-class problems using one-vs-one or one-vs-all, and builds an ensemble of RandBal ensembles. We call the two versions of the second

approach OVO-RandBal and OVA-RandBal, respectively. These two approaches were chosen because they are the most straightforward extensions of RandBal for multiple classes. Our main objective is to evaluate both approaches for multiclass imbalanced problems. To this end, an experiment was carried out with 52 multiclass data sets. The results suggest that both MultiRandBal, and OVO/OVA-RandBal are viable extensions of the original two-class RandBal. Collectively, they consistently outperform acclaimed state-of-the art methods for multiclass imbalanced problems. © 2019 Elsevier B.V.

Random forest model for feature-based Alzheimer's disease conversion prediction from early mild cognitive impairment subjects

Item Type Journal Article

Author M. Velazquez

Author Y. Lee

Abstract Alzheimer's Disease (AD) conversion prediction from the mild cognitive impairment (MCI) stage has been a difficult challenge. This study focuses on providing an individualized MCI to AD conversion prediction using a balanced random forest model that leverages clinical data. In order to do this, 383 Early Mild Cognitive Impairment (EMCI) patients were gathered from the Alzheimer's Disease Neuroimaging Initiative (ADNI). Of these patients, 49 would eventually convert to AD (EMCI_C), whereas the remaining 334 did not convert (EMCI_NC). All of these patients were split randomly into training and testing data sets with 95 patients reserved for testing. Nine clinical features were selected, comprised of a mix of demographic, brain volume, and cognitive testing variables. Oversampling was then performed in order to balance the initially imbalanced classes prior to training the model with 1000 estimators. Our results showed that a random forest model was effective (93.6% accuracy) at predicting the conversion of EMCI patients to AD based on these clinical features. Additionally, we focus on explainability by assessing the importance of each clinical feature. Our model could impact the clinical environment as a tool to predict the conversion to AD from a prodromal stage or to identify ideal candidates for clinical trials. © 2021 Velazquez et al. Rank classification method for cascade reservoirs considering scale, benefits, and risk consequences

Item Type Journal Article

Author T. Wang

Author Z. Li

Author W. Ge

Author Y. Zhang

Author Y. Jiao

Author L. Jing

Author P. van Gelder

Abstract Cascade reservoirs are essential in water resource utilization, flood control, and disaster mitigation. They have been built in several rivers worldwide. The rank classification for cascade reservoirs has significant practical implications for resource distribution decisions and risk management strategies and is also essential for ensuring the security of the basin. Internationally, reservoirs are typically classified based on project scale and dam failure consequences, whereas the risk transmission and superposition effect renders the classification method of reservoirs not directly applicable to cascade reservoirs. Therefore, to address this issue, this study proposed a rank classification method for cascade reservoirs. First, based on the scale, benefits, and risk consequences of dam failure, an index system for the rank classification of cascade reservoirs was established. Second, by constructing social risk criteria for cascade reservoirs and establishing a link among “project rank-reliability index-annual failure probability,” the allowable dam failure losses for different project ranks were determined. Thereafter, considering risk transmission and superposition, the rank classification standard and index quantification method for cascade reservoirs were proposed. Finally, five cascade reservoirs were selected for a feasibility study. The proposed method provides a supplement to the current rank classification standard of water conservancy projects in China and can also serve as a reference for risk assessment and classification management of cascade reservoirs in other countries. © 2023 Elsevier B.V.

Author Q.-N. Wu

Abstract *Euryales semen* (ES, *Euryale ferox* Salisb.) is a highly nutritious food, which is rich in starch. The quality of ES is usually affected by differences in geographic origin and variety. This study proposed a rapid classification and quantification method based on near-infrared, mid-infrared, and Raman spectroscopy combined with intelligent algorithms to achieve origin traceability and quality evaluation of ES. Traditional chemometrics initially classified ES from different regions and varieties using multispectral data. Machine learning algorithms combined with single and

fused datasets were successfully improved the performance of classification models. Random forest (RF) classifier constructed using the feature-level data fusion strategy exhibited optimal performance, with an accuracy of 94.74 % in origin traceability and 100 % in varietal traceability. Moreover, multispectral fingerprints were applied to rapidly determine the contents of total starch in ES. RF regression combined with fused dataset (near-infrared and mid-infrared fingerprints) produced optimal results, with the highest values for the ratio of prediction to deviation and coefficient of determination for prediction of 2.60 and 0.82, respectively. Overall, the proposed combination of multispectral fingerprints with intelligent algorithms shows great potential for origin determination and quality assessment of ES as well as of other foods and herbs. © 2025 Elsevier Inc.

Abstract Graphene has long been considered to have a wide application perspective in many fields, such as electronic information, chemical industry and aerospace. However, the actual graphene materials contain a variety of defects that affect their properties. Accurate and rapid identification of defect structure types is of great significance for the application of graphene. First, the image preprocessing technology is used to improve the classification precision. Next, use the convolutional neural network to classify the type of vacancy defect and perform rapid analytical tasks to accurately identify graphene defect structures. This study aims to contribute to this growing area of research in graphene to classify and count the vacancy defects automatically and quickly in monitoring its surface structures. © 2022 World Scientific Publishing Co. Rapid quantification of active pharmaceutical ingredient for sugar-free Yangwei granules in commercial production using FT-NIR spectroscopy based on machine learning techniques

Item Type Journal Article

Author J. Zhao

Author G. Tian

Author Y. Qiu

Author H. Qu

Abstract Rapid quantification methods for sugar-free Yangwei granules were developed based on near-infrared (NIR) spectroscopy combined with machine learning approaches as a quality control strategy for Chinese medicine granules (CMGs). Different machine learning approaches—i.e., interval partial least squares optimized by the genetic algorithm (GA-iPLS), the backpropagation artificial neural network (BP-ANN), and the particle swarm optimization-support vector machine (PSO-SVM)—were used to develop prediction models for three active pharmaceutical ingredients (APIs), namely, albiflorin, paeoniflorin, and benzoylpaeoniflorin. The partial least squares (PLS) algorithm was used for linear model calibration and comparison of the prediction performance of these developed models. The performance of the final models was assessed by the correlation coefficient (R), root mean square error of calibration set (RMSEC), and root mean square error of prediction set (RMSEP). All models performed well in model fitting and provided satisfactory prediction accuracy. The results indicate that the machine learning approaches are more stable, predictable, and suitable for CMGs when a high-accuracy analysis is required. In summary, NIR spectroscopy coupled with machine learning techniques is a suitable tool for the straightforward quantification of CMGs. © 2020 Elsevier B.V.

Rationalization of thermal injury quantification methods: Application to skin burns

Item Type Journal Article

Author B.L. Viglianti

Author M.W. Dewhirst

Author J.P. Abraham

Author J.M. Gorman

Author E.M. Sparrow

Abstract Classification of thermal injury is typically accomplished either through the use of an equivalent dosimetry method (equivalent minutes at 43 °C, CEM43 °C) or through a thermal-injury-damage metric (the Arrhenius method). For lower-temperature levels, the equivalent dosimetry approach is typically employed while higher-temperature applications are most often categorized by injury-damage calculations. The two methods derive from common thermodynamic/physical chemistry origins. To facilitate the development of the interrelationships between the two metrics, application is made to the case of skin burns. This thermal insult has been quantified by numerical simulation, and the extracted time-temperature results served for the evaluation of the respective characterizations. The simulations were performed for skin-surface exposure temperatures ranging from 60 to 90 °C, where each surface temperature was held constant for durations extending from 10 to 110 s. It was demonstrated that values of CEM43 at the basal layer of the skin were highly correlated with the depth of injury calculated from a thermal injury integral. Local

values of CEM43 were connected to the local cell survival rate, and a correlating equation was developed relating CEM43 with the decrease in cell survival from 90% to 10%. Finally, it was shown that the cell survival/CEM43 relationship for the cases investigated here most closely aligns with isothermal exposure of tissue to temperatures of ~50 °C. © 2013 Elsevier Ltd and ISBI.

RB-CCR: Radial-Based Combined Cleaning and Resampling algorithm for imbalanced data classification

Item Type Journal Article

Author M. Koziarski

Author C. Bellinger

Author M. Woźniak

Abstract Real-world classification domains, such as medicine, health and safety, and finance, often exhibit imbalanced class priors and have asynchronous misclassification costs. In such cases, the classification model must achieve a high recall without significantly impacting precision. Resampling the training data is the standard approach to improving classification performance on imbalanced binary data. However, the state-of-the-art methods ignore the local joint distribution of the data or correct it as a post-processing step. This can causes sub-optimal shifts in the training distribution, particularly when the target data distribution is complex. In this paper, we propose Radial-Based Combined Cleaning and Resampling (RB-CCR). RB-CCR utilizes the concept of class potential to refine the energy-based resampling approach of CCR. In particular, RB-CCR exploits the class potential to accurately locate sub-regions of the data-space for synthetic oversampling. The category sub-region for oversampling can be specified as an input parameter to meet domain-specific needs or be automatically selected via cross-validation. Our 5×2 cross-validated results on 57 benchmark binary datasets with 9 classifiers show that RB-CCR achieves a better precision-recall trade-off than CCR and generally out-performs the state-of-the-art resampling methods in terms of AUC and G-mean. © Crown 2021.

Re-assessing the “Classify and Count” Quantification Method

Item Type Conference Paper

Author A. Moreo

Editor Potthast M.

Editor Sebastiani F.

Abstract Learning to quantify (a.k.a. quantification) is a task concerned with training unbiased estimators of class prevalence via supervised learning. This task originated with the observation that “Classify and Count” (CC), the trivial method of obtaining class prevalence estimates, is often a biased estimator, and thus delivers suboptimal quantification accuracy. Following this observation, several methods for learning to quantify have been proposed and have been shown to outperform CC. In this work we contend that previous works have failed to use properly optimised versions of CC. We thus reassess the real merits of CC and its variants, and argue that, while still inferior to some cutting-edge methods, they deliver near-state-of-the-art accuracy once (a) hyperparameter optimisation is performed, and (b) this optimisation is performed by using a truly quantification-oriented evaluation protocol. Experiments on three publicly available binary sentiment classification datasets support these conclusions. © 2021, Springer Nature Switzerland AG.

Re-Thinking Classification Confidence with Model Quality Quantification

Item Type Conference Paper

Author Y. Pan

Author H. Zhao

Abstract Deep neural networks using for real-world classification task require high reliability and robustness. However, the Softmax output by the last layer of network is often over-confident. We propose a novel confidence estimation method by considering model quality for deep classification models. Two metrics, MQ-Repres and MQ-Discri are developed accordingly to evaluate the model quality, and also provide a new confidence estimation called MQ-Conf for online inference. We demonstrate the capability of the proposed method by the 3D semantic segmentation tasks using three different deep networks. Through confusion analysis and feature visualization we show the rationality and reliability of the model quality quantification method.¹¹This work is supported by the National Natural Science Foundation of China under Grant U22A2061 and High-performance Computing Platform of Peking University. © 2023 IEEE.

Real-time EEG-based emotion recognition using Riemannian quantification learning

Item Type Journal Article

Author B. Lv

Author Y. Yu

Author F. Zhuo

Author F. Tang

Abstract Emotion recognition via electroencephalogram (EEG) has obtained significant attention in many fields, including brain-computer interfaces. It is crucial to accurately identify emotional states in real-time scenarios with few-channel EEG signals and minimal user training data. This study tries to use symmetric positive definite (SPD) matrices to capture the characteristics of emotional EEG signals. We propose a classifier, termed as Riemannian robust soft learning vector quantization with the log-Euclidean metric learning (RRSLVQ-LEML), to distinguish the SPD matrices. To provide thorough analyses, we first evaluated the offline classification performance with channel selection and training data reduction across three public datasets, i.e., SEED, SEED-IV, and SEED-V. The results demonstrated that the proposed model outperformed the SPD network (SPDnet) significantly ($p < 0.05$). The classification accuracies on the three datasets using selected universal channels (22 channels) and a limited number of training samples (150 samples for each category) were $88.33\% \pm 5.77\%$, $76.05\% \pm 7.85\%$, and $70.62\% \pm 11.66\%$, respectively. We further validated the proposed model under the selected channel setup and a small amount of training in the online scenario by recruiting seven participants to conduct experiments for four-category emotion recognition. The average online classification accuracy was $77.28\% \pm 6.68\%$, which exhibited a strong linear correlation with the offline results ($r = 0.82$). These findings indicate that the RRSLVQ-LEML model is suitable for real-time emotion recognition with few EEG channels and minimal training samples. Furthermore, the offline performance evaluated by the RRSLVQ-LEML model is transferable to the online scenario. © 2025 The Authors

Real-Time PCR Quantification of Chloroplast DNA Supports DNA Barcoding of Plant Species

Item Type Journal Article
Author H.S. Kikkawa
Author K. Tsuge

Author R. Sugita

Abstract Species identification from extracted DNA is sometimes needed for botanical samples. DNA quantification is required for an accurate and effective examination. If a quantitative assay provides unreliable estimates, a higher quantity of DNA than the estimated amount may be used in additional analyses to avoid failure to analyze samples from which extracting DNA is difficult. Compared with conventional methods, real-time quantitative PCR (qPCR) requires a low amount of DNA and enables quantification of dilute DNA solutions accurately. The aim of this study was to develop a qPCR assay for quantification of chloroplast DNA from taxonomically diverse plant species. An absolute quantification method was developed using primers targeting the ribulose-1,5-bisphosphate carboxylase/oxygenase large subunit (rbcL) gene using SYBR Green I-based qPCR. The calibration curve was generated using the PCR amplicon as the template. DNA extracts from representatives of 13 plant families common in Japan. This demonstrates that qPCR analysis is an effective method for quantification of DNA from plant samples. The results of qPCR assist in the decision-making will determine the success or failure of DNA analysis, indicating the possibility of optimization of the procedure for downstream reactions. © 2016, Springer Science+Business Media New York.

Real-world adverse event analysis of Adagrasib: Insights from the FAERS database

Item Type Journal Article

Author S. Jian

Author S. Liang

Author X. Ma

Author S. Chen

Author X. Zhang

Author X. Lan

Author P. Zuo

Author E. Hou

Author S. Tu

Abstract Adagrasib is a potent and orally available small-molecule inhibitor that irreversibly targets the KRAS G12C mutant isoform. This innovative therapeutic agent represents a significant advancement in the field of oncology, offering a targeted approach to treating cancers driven by this specific mutation. The precision and potency of Adagrasib make it a promising candidate for improving patient outcomes in KRAS G12C-mutated cancers. However, alongside its therapeutic potential, it is crucial to

thoroughly understand and evaluate the safety profile of Adagrasib. The safety assessment includes a detailed examination of the adverse events (AEs) associated with its use. Comprehensive evaluation of these AEs is essential to ensure that the benefits of the drug outweigh any potential risks to patients. This retrospective pharmacovigilance study evaluated AEs associated with Adagrasib using data from the FDA adverse event reporting system database. We collected adverse drug reaction data for Adagrasib from the fourth quarter of 2022 to the first quarter of 2025. After standardizing the data, we applied several signal quantification methods, including the reporting odds ratio, proportional reporting ratio, Bayesian confidence propensity for neural networks, and Multi-item Gamma Poisson Shrinker (MGPS), for analysis. In this analysis of 556 adverse drug event reports where Adagrasib was identified as the primary suspect, we discovered 38 preferred terms across 20 system organ classifications. The 3 most prevalent system organ classifications were general disorders and administration site conditions, gastrointestinal disorders, and nervous system disorders. Notably, this study uncovered several new, previously unlabeled adverse reactions, including skin hyperpigmentation and seizures. These findings highlight the importance of ongoing pharmacovigilance to ensure comprehensive understanding of a drug's safety profile. These findings highlight the need for continued monitoring and understanding of Adagrasib potential risks. Further research is necessary to confirm these associations and address any previously unrecognized safety concerns. Copyright © 2025 the Author(s). Published by Wolters Kluwer Health, Inc.

Abstract Laser-induced breakdown spectroscopy (LIBS) is regarded as the future superstar for chemical analysis, but the relatively high measurement uncertainty and error remain the persistent challenges for its technological development as well as wide applications. In the present work, mechanisms of measurement uncertainty generation and basic principle of signal uncertainty and matrix effects impacting quantification performance were explained. Furthermore, methods for raw signal improvement

including sample preparation, system optimization, and especially plasma modulation, which modulates the laser-induced plasma evolution process for higher signal repeatability and signal-to-noise ratio, were reviewed and discussed. Different LIBS mathematical quantification methods including calibration-free methods and calibration methods, which were classified into physical-principle based calibration model, data-driven based calibration model, and hybrid model, were discussed and compared. Overall, a framework of quantification improvement strategy including key steps and main way-out was summarized and recommended for LIBS future development. © 2021 Elsevier B.V.

Recent developments in capabilities for analysing chlorinated paraffins in environmental matrices: A review

Item Type Journal Article

Author L.M. Van Mourik

Author P.E.G. Leonards

Author C. Gaus

Author J. De Boer

Abstract Concerns about the high production volumes, persistency, bioaccumulation potential and toxicity of chlorinated paraffin (CP) mixtures, especially short-chain CPs (SCCPs), are rising. However, information on their levels and fate in the environment is still insufficient, impeding international classifications and regulations. This knowledge gap is mainly due to the difficulties that arise with CP analysis, in particular the chromatographic separation within CPs and between CPs and other compounds. No fully validated routine analytical method is available yet and only semi-quantitative analysis is possible, although the number of studies reporting new and improved methods have rapidly increased since 2010. Better cleanup procedures that remove interfering compounds, and new instrumental techniques, which distinguish between medium-chain CPs (MCCPs) and SCCPs, have been developed. While gas chromatography coupled to an electron capture negative ionisation mass spectrometry (GC/ECNI-MS) remains the most commonly applied technique, novel and promising use of high resolution time of flight MS (TOF-MS) has also been reported. We expect that recent developments in high resolution TOF-MS and Orbitrap technologies will further improve the detection of CPs, including long-chain CPs (LCCPs), and the group separation and quantification of CP homologues. Also, new CP quantification methods have emerged, including the use of mathematical algorithms, multiple linear regression and principal component analysis. These quantification advancements are also reflected in considerably improved interlaboratory agreements since 2010. Analysis of lower chlorinated paraffins (<C15) remains, however, challenging and better approaches to analysing these homologues are needed. Furthermore, suitable quantification standards would facilitate improving the quality of CP analysis. © 2015 Elsevier Ltd.

Abstract Cover crops have critical significance for agroecosystem sustainability and have long been promoted in the U.S. Midwest. Knowledge of cover cropping variations and impacts of government policies remains very limited. We developed an accurate and cost-effective approach utilizing satellite fusion data, environmental variables, and machine learning to quantify cover cropping in corn and soybean fields from 2000 to 2021 in the U.S. Midwest. We found that cover crop adoption in most counties was stagnant from 2000 to 2011, but has significantly increased from 2011 to 2021. The adoption of 2021 is four times that of 2011, which was highly correlated to the funding for conservation programs. However, the percentage of cover crop adoption in the U.S. Midwest is still low (7.2%). Our work fills a critical gap in quantifying long-term field-level cover crop adoption at large regions and highlights the potential importance of incentive programs to promote sustainable agricultural practices. © 2022. Abstract Object identification and classification are vital in automation domains. It has gained conscience in the recent days owing to the growing domain of image processing and automation based on the growth of multiple sectors implementing automations. Object detection, identification and counting mechanisms are gaining momentum. Random urgencies and the trending algorithms of machine learning and deep learning strategies have made the object detection domain even more vulnerable. This paper implements a strategy to detect, classify and count objects based on image classification machine learning algorithms using Yolo. The proposed work considered training data collection using the app dataset, pre-processing using the DWT and GLCM, feature extraction using supervised ML algorithm, prune the available data and classification based on the proposed prediction models using R-CNN algorithms. The proposed methodology provided better accuracy with less computational overheads than the existing methods. © 2022, The Author(s), under exclusive license to Springer Nature Singapore Pte Ltd.

Recognition of hand gestures tracked by a dataglove: Exploiting Hidden Markov Models discriminative training and environment description to improve recognition performance

Item Type Conference Paper

Author V. Lippi

Author E. Ruffaldi

Author C.A. Avizzano

Author M. Bergamasco

Abstract Sequence classification based on Hidden Markov Models (HMMs) is widely employed in gesture recognition. Usually, HMMs are trained to recognize sequences by adapting their parameters through the Baum-Welch algorithm, based on Maximum Likelihood (ML). Several articles have pointed out that ML can lead to poor discriminative performances among gestures. This happens because ML is not optimal for this purpose until the modellized process is actually an HMM. In this paper we present a gesture recognition system featuring a discriminative training algorithm based on Maximal Mutual Information (MMI) and the integration of environment information. The environment is described through a set of fuzzy clauses, on the basis of which a priori probabilities are computed. Adaptive systems such as unsupervised neural networks are used to build a codebook of symbols representing the hand's states. An experiment on a set of meaningful gestures performed during the interaction with a virtual environment is then used to evaluate the performance of this solution.

Abstract The paper describes an automatic system for recognition of 10,000 plant species, with focus on species from the Guiana shield and the Amazon rain forest. The proposed system achieves the best results on the PlantCLEF 2019 test set with 31.9% accuracy. Compared against human experts in plant recognition, the system performed better than 3 of the 5 participating human experts and achieved 41.0% accuracy on the subset for expert evaluation. The proposed system is based on the Inception-v4 and Inception-ResNet-v2 Convolutional Neural Network (CNN) architectures. Performance improvements were achieved by: adjusting the CNN predictions according to the estimated change of the class prior probabilities, replacing network parameters with their running averages, test-time data augmentation, filtering the provided training set and adding additional training images from GBIF. © 2019 CEUR-WS. Reconciling Binary Replicates: Beyond the Average

Item Type Journal Article

Author H. Lorenzo

Author P. Pudlo

Author M. Royer-Carenzi

Abstract Binary observations are often repeated to improve data quality, creating technical replicates. Several scoring methods are commonly used to infer the actual individual state and obtain a probability for each state. The common practice of averaging replicates has limitations, and alternative methods for scoring and classifying individuals are proposed. Additionally, an indecisive response might be wiser than classifying all individuals based on their replicates in the medical context, where 1 indicates a particular health condition. Building on the inherent limitations of the averaging approach, three alternative methods are examined: the median, maximum penalized likelihood estimation, and a Bayesian algorithm. The theoretical analysis suggests that the proposed alternatives outperform the averaging approach, especially the Bayesian method, which incorporates uncertainty and provides credible intervals. Simulations and real-world medical datasets are used to demonstrate the practical implications of these methods for improving diagnostic accuracy and disease prevalence estimation. © 2026 The Author(s). Recovering true classifier performance in positive-unlabeled learning

Item Type Conference Paper

Author S. Jain

Author M. White

Author P. Radivojac

Abstract A common approach in positive-unlabeled learning is to train a classification model between labeled and unlabeled data. This strategy is in fact known to give an optimal classifier under mild conditions; however, it results in biased empirical estimates of the classifier performance. In this work, we show that the typically used performance measures such as the receiver operating characteristic curve, or the precisionrecall curve obtained on such data can be corrected with the knowledge of class priors; i.e., the proportions of the positive and negative examples in the unlabeled data. We extend the results to a noisy setting where some of the examples labeled positive are in fact negative and show that the correction also requires the knowledge of the proportion of noisy examples in the labeled positives. Using state-of-the-art algorithms to estimate the positive class prior and the proportion of noise, we experimentally evaluate two correction approaches and demonstrate their efficacy on real-life data. © Copyright 2017, Association for the Advancement of Artificial Intelligence (www.aaai.org). Editor Kourtellis N.

Editor Baralis E.

Abstract This paper proposes a novel approach for modeling observational data in the form of expert ratings, which are commonly given on an ordered (numerical or ordinal) scale. In practice, such ratings are often biased, due to the expert's preferences, psychological effects, etc. Our approach aims to rectify these biases, thereby preventing machine learning methods from transferring them to models trained on the data. To this end, we make use of so-called label smoothing, which allows for redistributing probability mass from the originally observed rating to other ratings, which are considered as possible corrections. This enables the incorporation of domain knowledge into the standard cross-entropy loss and leads to flexibly configurable models. Concretely, our method is realized for ordinal ratings and allows for arbitrary unimodal smoothings using a binary smoothing relation. Additionally, the paper suggests two practically motivated smoothing heuristics to address common biases in observational data, a time-based smoothing to handle concept drift and a class-wise smoothing based on class priors to mitigate data imbalance. The effectiveness of the proposed methods is demonstrated on four real-world goodwill assessment data sets of a car manufacturer with the aim of automating goodwill decisions. Overall, this paper presents a promising approach for modeling ordinal observational data that can improve decision-making processes and reduce reliance on human expertise. © 2023, The Author(s), under exclusive license to Springer Nature Switzerland AG.

Reduce false positives for human detection by a priori probability in videos

Item Type Conference Paper

Author L. Wang

Author X. Zhao

Author Y. Liu

Abstract In this work, we address the problem of reducing the false positives for human detection in videos. We employ the motion cue to build a foreground probability model. Then the mean expectation of the pixel-level foreground probability is computed to assign a priori probability to the sliding window in detection. We combine the response of Deformable Part Models and the mean probability expectation to form the features and train a linear classifier. The proposed approach is threshold-free, and reduces the false positives in human detection by the foreground cues. As well, we describe an integral probability image for fast computation of the mean probability expectation. Experimental results show that the proposed method achieve superior performance over the baseline of Deformable Part Models. © 2015 IEEE.

REDUCR: Robust Data Downsampling using Class Priority Reweighting

Item Type Conference Paper**Author** W. Bankes**Author** G. Hughes**Author** I. Bogunovic**Author** Z. Wang**Editor** Globerson A.**Editor** Mackey L.**Editor** Belgrave D.**Editor** Fan A.**Editor** Paquet U.**Editor** Tomczak J.**Editor** Zhang C.

Abstract Modern machine learning models are becoming increasingly expensive to train for real-world image and text classification tasks, where massive web-scale data is collected in a streaming fashion. To reduce the training cost, online batch selection techniques have been developed to choose the most informative datapoints. However, many existing techniques are not robust to class imbalance and distributional shifts, and can suffer from poor worst-class generalization

performance. This work introduces REDUCR, a robust and efficient data downsampling method that uses class priority reweighting. REDUCR reduces the training data while preserving worst-class generalization performance. REDUCR assigns priority weights to datapoints in a class-aware manner using an online learning algorithm. We demonstrate the data efficiency and robust performance of REDUCR on vision and text classification tasks. On web-scraped datasets with imbalanced class distributions, REDUCR significantly improves worst-class test accuracy (and average accuracy), surpassing state-of-the-art methods by around 15%. © 2024 Neural information processing systems foundation. Region-based evidential deep learning to quantify uncertainty and improve robustness of brain tumor segmentation

Item Type Journal Article

Author H. Li

Author Y. Nan

Author J. Del Ser

Author G. Yang

Abstract Despite recent advances in the accuracy of brain tumor segmentation, the results still suffer from low reliability and robustness. Uncertainty estimation is an efficient solution to this problem, as it provides a measure of confidence in the segmentation results. The current uncertainty estimation methods based on quantile regression, Bayesian neural network, ensemble, and Monte Carlo dropout are limited by their high computational cost and inconsistency. In order to overcome these challenges,

Evidential Deep Learning (EDL) was developed in recent work but primarily for natural image classification and showed inferior segmentation results. In this paper, we proposed a region-based EDL segmentation framework that can generate reliable uncertainty maps and accurate segmentation results, which is robust to noise and image corruption. We used the Theory of Evidence to interpret the output of a neural network as evidence values gathered from input features. Following Subjective Logic, evidence was parameterized as a Dirichlet distribution, and predicted probabilities were treated as subjective opinions. To evaluate the performance of our model on segmentation and uncertainty estimation, we conducted quantitative and qualitative experiments on the BraTS 2020 dataset. The results demonstrated the top performance of the proposed method in quantifying segmentation uncertainty and robustly segmenting tumors. Furthermore, our proposed new framework maintained the advantages of low computational cost and easy implementation and showed the potential for clinical application. © 2022, The Author(s).

Author L. Yuan

Abstract Context or problem: Balancing wheat production with improved nitrogen (N) use efficiency and reduced N loss depends on a clear understanding of fertilizer-N fate. However, integrative syntheses of 15N evidence across China's diverse wheat-growing regions remain scarce. Objective and methods: Using a compiled database of 421 observations from 86 published 15N field tracer studies in China's wheat systems, we integrated meta-analysis with machine learning to quantify the effects of climate, soil, and N management factors on wheat yield and 15N fate, and to predict region-specific attainable 15N uptake potential. Results and conclusions: Wheat yield under N fertilization (52.5–489.0 kg N ha⁻¹) averaged 6874.02 kg ha⁻¹ nationwide, with fertilizer-15N exhibiting uptake, residual, and loss percentages of 37.29%, 31.53%, and 31.35%, respectively. Regionally, wheat yield ranked as Central China (CC) > Southern China (SC) > Northern China (NC), whereas fertilizer-15N uptake% ranked as CC > NC > SC. Random forest (RF) analysis showed different dominant drivers for yield (SOM, MAT, and BD) and fertilizer-15N uptake% (TN, MAP, and soil pH), suggesting that the inconsistent regional patterns between yield and fertilizer-15N uptake% may be partly attributable to differences in soil fertility and hydroclimatic conditions. Spatial prediction was used to estimate attainable fertilizer-15N uptake, defined as RF-predicted 15N uptake% based on gridded predictors representing broad spatial gradients. Regional attainable uptake was 46.76%, 51.67%, and 49.86% in NC, CC, and SC, respectively, with attainable–observed fertilizer-15N uptake differences of 10.24, 12.36, and 17.45 %age points. Implications: These findings provide a scientific basis for region-specific optimization of N management to enhance 15N uptake under local climatic and soil conditions, supporting sustainable precision agriculture. © 2026 Elsevier B.V.

Regularization-based methods for ordinal quantification

Item Type Journal Article

Author M. Bunse

Author A. Moreo

Author F. Sebastiani

Author M. Senz

Abstract Quantification, i.e., the task of predicting the class prevalence values in bags of unlabeled data items, has received increased attention in recent years. However, most quantification research has concentrated on developing algorithms for binary and multi-class problems in which the classes are not ordered. Here, we study the ordinal case, i.e., the case in which a total order is defined on the set of $n > 2$ classes. We give three main contributions to this field. First, we create and make available two datasets for ordinal quantification (OQ) research that overcome the inadequacies of the previously available ones. Second, we experimentally compare the most important OQ algorithms proposed in the literature so far. To this end, we bring together algorithms proposed by authors from very different research fields, such as data mining and astrophysics, who were unaware of each others' developments. Third, we propose a novel class of regularized OQ algorithms, which outperforms existing algorithms in our experiments. The key to this gain in performance is that our regularization prevents ordinally implausible estimates, assuming that ordinal distributions tend to be smooth in practice. We informally verify this assumption for several real-world applications. © The Author(s) 2024.

Regularized learning for domain adaptation under label shifts

Item Type Conference Paper

Author K. Azizzadenesheli

Author F. Yang

Author A. Liu

Author A. Anandkumar

Abstract We propose Regularized Learning under Label shifts (RLLS), a principled and a practical domain-adaptation algorithm to correct for shifts in the label distribution between a source and a target domain. We first estimate importance weights using labeled source data and unlabeled target data, and then train a classifier on the weighted source samples. We derive a generalization bound for the classifier on the target domain which is independent of the (ambient) data dimensions, and instead only depends on the complexity of the function class. To the best of our knowledge, this is the first generalization bound for the label-shift problem where the labels in the target domain are not available. Based on this bound, we propose a regularized estimator for the small-sample regime which accounts for the uncertainty in the estimated weights. Experiments on the CIFAR-10 and MNIST datasets show that RLLS improves classification accuracy, especially in the low sample and large-shift regimes, compared to previous methods. © 7th International Conference on Learning Representations, ICLR 2019. Rehabilitation exergames: Use of motion sensing and machine learning to quantify exercise performance in healthy volunteers

Item Type Journal Article

Author R.H. Osgouei

Author D. Soulsby

Author F. Bello

Abstract Background: Performing physiotherapy exercises in front of a physiotherapist yields qualitative assessment notes and immediate feedback. However, practicing the exercises at home lacks feedback on how well patients are performing the prescribed tasks. The absence of proper feedback might result in patients performing the exercises incorrectly, which could worsen their condition. We present an approach to generate performance scores to enable tracking the progress by both the patient at home and the physiotherapist in the clinic. Objective: This study aims to propose the use of 2 machine learning algorithms, dynamic time warping (DTW) and hidden Markov model (HMM), to quantitatively assess the patient's performance with respect to a reference. Methods: Movement data were recorded using a motion sensor (Kinect V2), capable of detecting 25 joints in the human skeleton model, and were compared with those of a reference. A total of 16 participants were recruited to

perform 4 different exercises: shoulder abduction, hip abduction, lunge, and sit-to-stand exercises. Their performance was compared with that of a physiotherapist as a reference. Results: Both algorithms showed a similar trend in assessing participant performance. However, their sensitivity levels were different. Although DTW was more sensitive to small changes, HMM captured a general view of the performance, being less sensitive to the details. Conclusions: The chosen algorithms demonstrated their capacity to objectively assess the performance of physical therapy. HMM may be more suitable in the early stages of a physiotherapy program to capture and report general performance, whereas DTW could be used later to focus on the details. The scores enable the patient to monitor their daily performance. They can also be reported back to the physiotherapist to track and assess patient progress, provide feedback, and adjust the exercise program if needed. ©Rachel K Nelligan, Rana S Hinman, Pek Ling Teo, Kim L Bennell.

Abstract Aortic stenosis (AS) quantification relies on transvalvular gradients or aortic valve opening area (AVA), two measures that inherently depend on the instantaneous transvalvular flow rate (Q). We present a new quantification method for AS based on new modeling where AVA saturates with increasing Q, contradicting the assumption of linear Q-AVA relation currently predominant in the literature. The objective of this study is the development of a new method for the quantification of AS. In 141 patient undergoing transesophageal echocardiography, AVA was obtained frame-by-frame over an entire systole from 3-D echocardiograms using multiplanar reconstruction. Q was retrieved by Doppler- and 3-D echocardiography of the left ventricular outflow tract. A sigmoid Q-AVA relation was fitted with a machine learning algorithm. The measured and the predicted AVA were compared between a parametrized linear and sigmoid Q-AVA relation model. A relative aortic valve stiffness (rAVS) was calculated, and an isostiffness nomogram was constructed. Cox proportional hazard modeling was used to look for predictors of rehospitalization-free survival. Compared with the linear model, the sigmoid model consistently better predicted measured AVA in all AS severity groups. Within severity groups, rAVS remained robust and constant, a property not shared by the linear model. A receiver operating characteristic (ROC)-analysis revealed a rAVS value of 1.51 as the best cut-off for distinguishing severe from nonsevere AS. Cox proportional hazard modeling showed its value as an independent predictor of rehospitalization-free survival. We present a new method for the quantification of AS that could help simplify the diagnosis of patients with low-flow, low-gradient AS. Copyright © 2026 The Authors.

Author G.D. Brand

Abstract Background: Type II Congenital Disorders of Glycosylation (CDG-II) are a group of diseases with challenging diagnostics characterized by defects in the processing of glycans in the Golgi apparatus. Mass Spectrometry (MS) has been a valuable tool in the definition of CDG-II subtypes. While some CDG-II subtypes are associated with specific N-glycan structures, others only produce changes in relative levels, reinforcing the demand for quantification methods. Methods: Plasma samples from control individuals were pooled, derivatized with deuterated iodomethane (I-CD 3),

and used as internal standards for controls and patients whose glycans were derivatized with iodomethane (I-CH₃), followed by MALDI MS, LC-MS and -MS/MS analyses. Results: Total N-glycans from fifteen CDG-II patients were evaluated, and 4 cases with molecular diagnosis were considered in detail: 2ATP6V0A2-CDG siblings, and 2 MAN1B1-CDG patients, one of them carrying a previously undescribed p.Gly536Val mutation. Conclusions: Our methodology offers a feasible alternative to the current methods for CDG-II diagnosis by MS, which quantify glycan structures as fractions of the total summed signal across a mass spectrum, a strategy that lowers the variability of minor components. Moreover, given its sensitivity for less concentrated yet biologically relevant structures, it might assist the uncovering of novel diagnostic glycans in other CDG-II subtypes. © 2019 Elsevier B.V.

Reliability assessment framework based on feature separability for pathological cell image classification under prior bias

Item Type Journal Article

Author K. Yamashita

Author Y. Kakeji

Abstract Background and objective: Prior probability shift between training and deployment datasets can compromise deep learning-based medical image classification, and standard posterior reweighting is not uniformly beneficial. We developed a feature-separability-based reliability assessment framework to identify when prior correction is likely to improve pathological cell classification. Methods: We analysed 303 colorectal cancer specimens with CD103/CD8 dual immunostaining, generating 171,638 annotated cell images across 19 cell types. After class-capped, imbalance-reduced sampling, 16 cell types were evaluated using ResNet models trained under controlled prior-bias conditions. Feature separability was quantified using cosine similarity-based likelihood quality scores derived from intra-class and inter-class relationships in learned embedding spaces. Associations with F1 performance were examined together with prior-bias magnitude and sample adequacy. Results: Feature separability was the dominant predictor of F1 performance in the multivariable model ($\beta=1.650$, $p<0.001$), whereas prior-bias magnitude showed a much smaller effect ($\beta=0.004$, $p=0.018$). A likelihood-quality threshold of 0.294 provided an empirical operating point for identifying cases likely to benefit from correction. Overall, 78.0% of cases showed no improvement after correction, indicating that correction should not be applied uniformly. Supplementary ViT and UNI analyses showed the same broad separability-reliability relationship. Conclusion: Feature separability, rather than prior-bias magnitude alone, determined when prior correction improved classification performance. The proposed framework supports selective correction decisions during labelled validation, with task-specific thresholds requiring recalibration for other datasets. Copyright © 2026. Reliability assessment of guided wave damage localization with deep learning uncertainty quantification methods

Item Type Journal Article

Author I.D. Khurjekar

Author J.B. Harley

Abstract Guided wave-based structural health monitoring is an attractive option for detecting structural defects in an automated manner. In this work, we focus on the task of damage localization. Deep learning methods have been shown to have superior performance for damage localization. Yet, environmental variations introduce uncertainty in the system and reduce its reliability. For this reason, it is crucial to assess the reliability of estimates taken from structural health monitoring systems. In this work, we estimate the localization reliability from a single snapshot of sparse array guided wave measurements instead of reporting values averaged over an entire set of test measurements. The assessment strategy can be added to any deep learning localization model and produces both a localization and uncertainty estimate. The

deep learning model is trained using only guided wave simulations. We assess the uncertainty using both simulated and experimental data with temperature variations. Multiple deep learning-based uncertainty quantification methods are analyzed. Results demonstrate correlations between uncertainty, temperature variations, and the presence of synthetic damage. We also compare with reliability derived from delay-and-sum localization. We find that a deep ensemble learning strategy provides the most reliable damage localization and uncertainty quantification. © 2024 Elsevier Ltd

Reliable predictions in the wild: A confidence-aware prior injection for mitigating distributional risks

Item Type Journal Article

Author J. Zhang

Author P. Li

Author G. Zhang

Author X. Gao

Author P. Gong

Abstract Few-shot classifiers deployed in safety-critical environments are highly vulnerable to distributional shifts, particularly when facing simultaneous label shift and open-set contamination. These conditions compromise decision integrity, causing models to misinterpret potential outliers or open-set samples as high-confidence known classes. A conventional defense is to estimate the test-time prior and inject it globally into classifier logits. However, we identify that this uniform correction introduces a brittleness in the inference pipeline: it creates a trade-off where strengthening the prior to correct in-distribution shifts inadvertently over-corrects ambiguous or adversarial-like queries, increasing the risk of harmful prediction flips. To harden few-shot systems against these distributional risks, we introduce Piecewise- π , a lightweight inference-time defense module. Unlike rigid global injection, Piecewise- π employs a confidence-aware mechanism that partitions queries based on their reliability. It applies a defensive, conservative correction to low-confidence queries (which are statistically likely to be outliers) while enforcing stronger calibration only on high-confidence, verified predictions. Experiments on CIFAR and STL benchmarks under severe imbalance and contamination demonstrate that Piecewise- π significantly improves the risk-coverage trade-off and system reliability without retraining the backbone. Behavioral analysis confirms that Piecewise- π effectively minimizes harmful decision reversals, offering a computationally efficient strategy to secure classifier performance in dynamic, open environments. © 2026 Elsevier Ltd.

Abstract Effective reduction of oceanic plastic pollution requires scalable and objective monitoring methods that go beyond traditional human-based surveys. This review synthesizes recent advances in remote sensing and AI-driven image analysis for detecting macro-plastic litter. Peer-reviewed studies published up to 2024 were systematically selected from the Scopus database, focusing on applications of remote sensing platforms including webcams, drones, balloons, aircraft, and satellites for monitoring plastic litter in coastal, riverine, and other aquatic environments. Quantification methods ranged from manual annotation to deep learning-based models. Although machine learning has been increasingly adopted since around 2020, manual screening and rule-based approaches remain prevalent, reflecting the complexity of litter types and shapes. The review revealed considerable variability in quantification metrics—such as litter-covered area, volume, weight, and item count per unit area—which complicates cross-study comparisons and data harmonization. While remote sensing enhances spatial coverage, consistency, and repeatability, it faces persistent challenges, including environmental interference, limited resolution, and inconsistent protocols. Our findings highlight the urgent need for methodological standardization and harmonization of quantification units across platforms and geographic regions. Among available metrics, litter-covered area and item count per unit area are most suitable for cross-platform comparison. Continued development and integration of such technologies hold strong potential to facilitate science-based policymaking and long-term monitoring of plastic transport from land to ocean. © 2025 The Authors

Abstract In order to meet the 1.5 °C temperature control target of the Paris Agreement and the implementation requirements of carbon tariff policy, this paper builds a multi-modal remote sensing monitoring framework for carbon neutrality, breaking through the technical bottlenecks of traditional methods in emission traceability accuracy (error > 5%) and dynamic timeliness of carbon sinks (quarterly update). The framework design includes: a multi-modal spatio-temporal fusion model integrating Landsat8, Sentinel-5P TROPOMI and ERA5 data, and using the radiative transfer equation to correct the scale difference, the spatial positioning accuracy of point source emissions is less than 1 km; A dynamic carbon sink assessment algorithm based on the coupling model of NDVI and soil organic carbon was proposed. The parameter sensitivity (NDVI contribution 62.3%) was optimized by machine learning to quantify the interannual change rate of carbon sink. Edge computing monitoring system based on federated learning architecture, realizing hourly data update and response delay < 2 h. The multi-dimensional test verification of the Beijing-Tianjin-Hebei Demonstration zone showed that the F1-score of the industrial point source reached 0.89 (23.6% higher than that of the traditional method), the RMSE of the carbon sink decreased to 0.34 MtC/km² (65% less error), and the system covered 12 provinces and administrative regions and identified 1235 hidden emission sources. Significant contribution to research innovation: pioneered the three-level fusion paradigm of “radiative transfer, deep learning and federal computing” to support accurate carbon tariff accounting; Develop a dynamic monitoring system for subkilometer carbon sinks to meet the needs of global carbon budget verification under the Paris Agreement; Prototype a scalable global monitoring network to provide the technical tools to achieve UNFCCC goals. © The Author(s), under exclusive license to Springer Nature Switzerland AG 2026.

Resampling ensemble algorithm for class imbalance problem using optimization algorithm

Item Type Journal Article**Author** S. Lavanya**Author** S. Palaniswami**Author** M. Divyabharathi

Abstract Learning classifiers from imbalanced data has attracted a significant amount of interest in recent years. The imbalanced class in the dataset problem is a special type of classification problem where the class priors are highly unequal and imbalanced. Resampling ensemble algorithm is developed focused on the classification problems for imbalanced datasets. The small classes are over sampled by the use of SMOTE (Synthetic Minority Oversampling Technique) algorithm and large classes are under-sampled where the samples are to be selected randomly from the majority class data. The optimization technique has been introduced on the oversampling and undersampling process in imbalanced classification. The aim is to study the use of Optimization Technique to improve the performance of imbalanced classification. A novel approach called as BAT Algorithm for over and under sampling (BAOUS) technique where the accuracy rate of all the classes is optimized at the same time. From the experimental result, the system is used to reduce the time complexity as well as it will enhance the accuracy rate of the imbalance classification result. © Research India Publications.

Abstract The quality of drilling wellbore is crucial for oilfield companies to evaluate the construction acceptance of drilling operations, evaluate the wellbore quality before cementing operations, and smoothly implement subsequent casing and electrical logging tools. At present, the evaluation of wellbore quality only requires dispersed trajectory parameters of different well sections (well inclination angle, dog leg angle, target range), and only considers whether the trajectory parameters are within the qualified range during completion acceptance. A quantitative scoring method for wellbore quality has not yet been developed, which is not conducive to the evaluation of well quality by oilfield enterprises during drilling completion acceptance. In this paper, the key parameters such as deviation measurement interval, dogleg degree, maximum deviation and target hit are comprehensively considered. Based on the comprehensive method of mathematical statistics and Matlab programming calculation, a multi-level quantitative scoring model of well bore quality is established. The key parameters in the multi-level quantitative model of well bore quality are determined by using the main control factor analysis method of random forest algorithm. Taking the A oil field as an example, a quantitative scoring was conducted on the quality of 74 drilled wells in 2021 to evaluate the effectiveness of the operation team in controlling well quality. The analysis results showed that for the A oil field, the importance of factors affecting well quality was as follows: maximum inclination > Target radius > dog leg = survey interval. Crew 1 had better control over well quality, and the proportion of high-quality wells in 2021 decreased compared to 2020, The analysis results of

the multi-level well bore quality quantification method based on random forest algorithm proposed in this paper are in line with the field work practice, which provides a theoretical basis for well bore quality quantification, and is of great significance for the process management and efficiency improvement in oil fields. © The Author(s), under exclusive license to Springer Nature Singapore Pte Ltd. 2024.

Research into the Influence Mechanisms of Visual-Comfort and Landscape Indicators of Urban Green Spaces

Item Type Journal Article

Author Y. Meng

Author J. Shi

Author M. Lyu

Author D. Sun

Author H. Fukuda

Abstract Urban green spaces play a crucial role in providing social services and enhancing residents' mental health. It is essential for sustainable urban planning to explore the relationship between urban green spaces and human perceptions, particularly their visual comfort. However, most current research has analyzed green spaces using two-dimensional indicators (remote sensing), which often overlook human visual perceptions. This study combined two-dimensional and three-dimensional methods to evaluate urban green spaces. Additionally, the study employed machine learning to quantify residents' visual comfort in green-space environments and explored the relationship between green spaces and human visual perceptions. The results indicated that Kitakyushu exhibited a moderate FCV and an extremely low Green View Index (GVI). Yahatanishi-ku was characterized as having the highest visual comfort. Tobata-ku demonstrated the lowest visual comfort. Natural, GVI, openness, enclosure, vegetation diversity, landscape diversity, and NDBI were positively correlated with visual comfort. FCV and ENVI were negatively correlated with visual comfort. Vegetation diversity had the most impact on improving visual comfort. By integrating remote sensing and street-view data, this study introduces a methodology to ensure a more holistic assessment of green spaces. Urban planners could use it to better identify areas with insufficient green space or areas that require improvement in terms of green-space quality. Meanwhile, it could be helpful in providing valuable input for formulating more effective green-space policies and improving overall urban environmental quality. The study provides a scientific foundation for urban planners to improve the planning and construction of healthy and sustainable cities. © 2024 by the authors.

Research on an Intelligent Prediction Method for the Carbon Emissions of Prefabricated Buildings During the Construction Stage, Based on Modular Quantification

Item Type Journal Article

Author Y. Yang

Author X. Cai

Author X. Ma

Author G. Yao

Author T. Lei

Author H. Tan

Author Y. Wang

Abstract Prefabricated buildings are widely utilized due to their effectiveness in reducing carbon emissions. The construction stage has a significantly higher carbon emission rate than the other stages of their life cycle, but this is difficult to accurately quantify and predict due to the high variability. This study clarifies the system boundary of carbon emissions and the parameters of influence in carbon emissions predictions. The carbon emission quantification model was improved by using the process analysis method and the carbon emission factor method, and a modular calculation formula was proposed. Based on the machine learning algorithm, a carbon emissions prediction model for prefabricated buildings' construction stage was established and hyperparameter optimization was conducted. A sample database for predicting prefabricated buildings' carbon emissions during the construction stage was established using a modular quantification method, and the thin plate spline interpolation algorithm was introduced to expand this. The prediction results of carbon emission prediction models using four algorithms, SVR, BPNN, ELM, and RF, were compared and analyzed by RMSE and R2. The results show that the model based on BPNN has the highest prediction accuracy when determining the carbon emissions of prefabricated building during the construction stage, and this method can provide a more accurate reference for subsequent quantitative research on carbon emissions from prefabricated buildings. © 2025 by the authors.

Research on Data Security Analysis and Label Recognition Technology Based on Big Data Business Scenario

Item Type Conference Paper**Author** D. Liu**Author** D. Kong**Author** X. Liu**Author** L. Ma**Author** Y. Chang**Author** H. Zhang**Author** R. Wang**Author** H. Yu**Editor** Li W.**Editor** Zhang X.

Abstract Data is the inevitable product of social high informatization, and its security risk is an indispensable part of information security. In the case of accelerating the construction of ubiquitous power Internet of things, this paper deeply studies the

data security analysis and label recognition technology based on big data business scenarios. Based on the process of active and passive discovery, a complete catalog of data assets is established by means of database scanning, server scanning, terminal scanning, terminal monitoring, network monitoring and database access monitoring. The threat tree is used to model various threats to data security. On the basis of data asset cataloging and threat modeling, this paper studies the data security risk analysis and quantification method by comprehensively judging the threats faced by the business system, as well as the vulnerability and asset value of the system itself. Based on the heuristic integrated learning strategy of automatic semantic tagging for massive network resources, metadata is extracted through active and passive collection, and the semantic relationship between tags is extracted and processed by natural language processing and machine learning technology. Finally, automatic labels are generated through analysis capabilities such as business correlation analysis, organizational correlation analysis, data distribution analysis, data classification and grade. © 2020 IEEE.

Research on Generative Language Models Aiding Project Quantification Methods

Item Type Conference Paper

Author F. Gao

Abstract With the construction of digital projects, the Work Breakdown Structure (WBS)-based review system plays an important role in the feasibility study review of projects. Therefore, the main objective is to design a set of methods and a review system for quantifying the influence factors of feasibility study review projects based on digital technology. This is intended to address the issue in the existing project review system where the verification of influence factors mainly relies on experts' experience, making it difficult to achieve objectivity and accuracy. This technology will use Natural Language Understanding (NLU) technology to analyze the textual descriptions of project functions, identify key entities and actions, and then match them with pre-defined rule abstraction models to determine the corresponding fixed influence factors. In addition, multiple methods will be employed to quantify floating influence factors, including traditional machine learning prediction models, large language model-based semantic similarity-weighted influence factors, and generative large model-based automatic code generation evaluation. © 2025 Author(s).

Abstract As the number of electric vehicles increases year by year, electric vehicles can be used as energy storage equipment to optimize the grid load curve. Studying the interactive potential evaluation and quantification methods of electric vehicles as adjustable resources to participate in grid mobilization and operation has far-reaching significance for the optimal operation of electric vehicles and grid load. This paper is based on the historical operation data of all electric vehicles in Shanghai, collected by the Internet of Vehicles detection platform. First, classify electric vehicles as adjustable resources in interaction, and build corresponding indicator system based on classification. Secondly, the evaluation method and quantitative method are given according to the classification. Finally, an example is simulated based on the data. The simulation results show that the electric vehicles in Shanghai, as an interactive and adjustable resource for grid operation, have the potential to optimize the grid operation curve in peak shaving and valley filling. © 2023, The Author(s), under exclusive license to Springer Nature Singapore Pte Ltd.

Research on Intrusion Detection Based on Interpretable Machine Learning

Item Type Conference Paper

Author M. Chen

Author B. Ma

Author H. Jiang

Abstract Intrusion Detection Systems (IDS) grapple with challenges such as delayed updates and a high false positive rate in traditional rule-based approaches under high-dimensional network traffic data. Although deep learning has significantly improved detection accuracy, the conflict between its "black box" nature and traceability requirements still persists. This paper focuses on port scanning attack detection and provides a "dual-wheel-driven" solution of "architecture optimization and interpretability enhancement" to build a high-precision interpretable learning framework. To tackle the vanishing gradient and overfitting problems of traditional Deep Neural Networks (DNN), an enhanced DNN model architecture is designed: through dynamic residual structure, "expansion-compression" design, and adaptive regularization strategy, the learning ability of high-dimensional network traffic features is improved. Moreover, to address the common "black-box" problem in current models, this paper introduces a feature importance quantification method based on gradient-weighting, which integrates

dynamic prediction confidence weights to enhance the interpretability analysis of model decisions. In this study, the CICIDS-2017 dataset is chosen for training and evaluation. The results indicated that the enhanced DNN model had significantly better accuracy on the test set than traditional DNN and traditional machine learning models. More importantly, the enhanced DNN model can also identify key attack features, providing high-precision and transparent methodological support for cybersecurity defense. © 2025 Copyright held by the owner/author(s).

Research on Landslide Risk Assessment of Mountainous Highways

Item Type Journal Article
Author H.-J. Wen
Author F.-Y. Yan
Author J.-Y. Zhao
Author Y. Liu

Abstract Aiming at the problems that there is a lack of a comprehensive assessment framework for landslide risks of mountainous expressways and existing studies only focus on landslide susceptibility, which makes it difficult to fully support risk management and control, this study intends to construct a scientific landslide risk assessment system for mountainous expressways. Based on Geographic Information System (GIS) technology, this study proposes a three-dimensional assessment framework integrating “landslide susceptibility of slope units-vulnerability of expressways-exposure”. Specifically, firstly, combined with the landslide triggering mechanism and engineering geological survey data, 15 landslide influencing factors including elevation, slope gradient and slope position were selected, and a LightGBM landslide susceptibility evaluation model was constructed using the semi-supervised learning method. Secondly, by quantifying the traffic volume after road completion and the economic losses that may be caused by the damage of different structures, 5 vulnerability indicators were determined, including life loss, vehicle loss, direct loss of expressway structures, repair costs and indirect loss caused by traffic interruption. The entropy weight method was used to calculate the weight of each indicator to complete the vulnerability evaluation. Finally, the exposure of the expressway was characterized by the area of the slope unit where the road affected by landslides is located and the average distance from the slope unit to the road. By multiplying susceptibility, vulnerability and exposure, this study realized the quantitative comprehensive assessment of landslide risks of mountainous expressways. This study breaks through the limitation of traditional studies that only focus on landslide susceptibility, and constructs a “susceptibility-vulnerability-exposure” trinity comprehensive assessment framework for landslide risks of mountainous expressways. Moreover, the selection and quantification methods of indicators in each dimension are more in line with practical engineering scenarios. The research results can provide methodological support for the comprehensive assessment of landslide risks, and at the same time offer a scientific basis for the mitigation, control and risk management decision-making of landslide risks of mountainous expressways. © (2024), (Chang'an University). Research on Network Security Evaluation and Optimal Active Defense based on Attack and Defense Game Model in Big Data Era

Item Type Conference Paper

Author X. Ge

Abstract Due to the increasing progress of socialist modernization and the increasing progress of social productivity, the national computer industry has developed rapidly in recent years, and has become the main driving force to promote China's economic development. Facing the increasingly complex network environment, the traditional network security technology can not effectively resist the existing network attacks. Low defense and high memory consumption are two disadvantages of traditional network information security assessment. In essence, network security is the process of mutual game between network attackers and network defenders. In the process of mutual game, if one party benefits, it is the winner. In order to carry out the security evaluation and active defense of network information system, the network defense graph model, the classification of attack and defense strategies and their cost quantification method, the network attack and defense game model and the optimal active defense selection algorithm based on the above model are proposed. Based on the attack and defense game theory, this paper analyzes the network security evaluation and optimal active defense methods by establishing a model © 2022 ACM.

Research on Offline Classification and Counting Algorithm of Long Fitness Video

Item Type Conference Paper

Author Z. Zheng

Author Z. Ma

Abstract With the holding of sports events such as the Winter Olympics, "fitness" has once again become a key topic of widespread concern. Scientific fitness has become a new requirement when people engage in fitness activities today. Scientific and efficient fitness guidance is often inseparable from the support of personal exercise data. At present, the motion data quantification method for motion recognition and counting through wearable devices such as sensors has problems such as poor convenience and poor visualization. This paper uses deep learning methods to study motion classification and counting, which makes up for the shortcomings of traditional quantification methods. The purpose of this paper is to identify and count five common types of exercises in long videos: squats, sit-ups, push-ups, pull-ups, and jumping jacks. The main work and innovations are as follows: (1) This paper proposes an algorithm for motion classification and counting based on long videos. The algorithm first uses the temporal action detection model MPGCN proposed in this paper to locate and classify valid segments of long videos, and then uses the ATRepNet motion counting model

proposed in this paper to count the cropped valid segments. (2) The large difference between the action duration and the action amplitude in the long video leads to the deterioration of the effect of the time-series action detection model. In view of this, this paper designs a MS multi-scale graph convolution layer which is integrated into the PGCN model for graph convolution multi-scale information fusion, and the MPGCN model is proposed. Finally, the mean Average Precision (mAP) of the localization and classification of dual-stream features in the public dataset is improved by 1.2%. (3) The complex video background in this scene leads to poor counting accuracy. In response to this, this paper improves the hybrid attention mechanism and integrates it into the counting model RepNet, and proposes the ATRepNet model. Finally, on the self-made test dataset, the counting accuracy is improved by 1.5%. © 2022 IEEE.

RESEARCH ON PULSE EDDY CURRENT DETECTION TECHNIQUE OF THINNING DEFECTS IN THE ALUMINUM-STEEL STRUCTURE OF WING WALL PLATE

Item Type Journal Article**Author** T. Chen**Author** Y. Yin**Author** C. Lv**Author** X. Song**Author** Z. Deng**Author** Q. Wu

Abstract Owing to the variation in metal activity, the aluminum-steel structure of wing wall panels is particularly susceptible to galvanic corrosion. Because of the concealed nature of the defects and the significant disparity in the physical properties of the materials, detecting thinning defects in aluminum-steel structures proves highly challenging. To tackle these issues, this study introduces a pulsed eddy current detection technique capable of accurately identifying various types of thinning defects within aluminum-steel structures. First, finite element simulation software is employed to establish the detection model, constructing the mapping relationship between the characteristic signal and thinning through simulation signal analysis. Second, the defect identification classification space and the inversion curve for thinning are developed. Finally, a pulsed eddy current detection system is developed to validate the proposed defect classification and quantification method. Experimental results demonstrate that the method effectively identifies and quantifies various thinning defects in the aluminum-steel structures of wing wall panels. ©2025 American Society for Nondestructive Testing.

Research on Risk Quantification Methods for Connected Autonomous Vehicles Based on CNN-LSTM

Item Type Journal Article

Author K. Wang

Author D. Qu

Author D. Shao

Author L. Wei

Author Z. Zhang

Abstract Quantifying and predicting driving risks for connected autonomous vehicles (CAVs) is critical to ensuring the safe operation of traffic in complex environments. This study first establishes a car-following model for CAVs based on molecular force fields. Subsequently, using a convolutional neural network and long short-term Memory (CNN-LSTM) deep-learning model, the future trajectory of the target vehicle is predicted. Risk is quantified by employing models that assess both the collision probability and collision severity, with deep-learning techniques applied for risk classification. Finally, the High-D dataset is used to predict the vehicle trajectory, from which the speed and acceleration of a target vehicle are derived to forecast driving risks. The results indicate that the CNN-LSTM model, when compared with standalone CNN and LSTM models, demonstrates a superior generalization performance, a higher sensitivity to risk changes, and an accuracy rate exceeding 86% for medium- and high-risk predictions. This improved accuracy and efficacy contribute to enhancing the overall safety of connected vehicle platoons. © 2024 by the authors.

Research on safety risk assessment index system for low-altitude flight in urban dense areas

Item Type Conference Paper

Author W. Xiaoning

Author J. Zhe

Author F. Tiegang

Abstract With the rapid proliferation of low-altitude aircraft in urban dense areas, their safety risks have become a critical constraint on industry development. Based on a four-dimensional framework encompassing technology, environment, operations, and management, this paper proposes a set of safety risk identification and classification indicator systems for low-altitude flight in urban dense areas. Through literature analysis, historical data mining, and expert assessment, we systematically identified multiple typical risk sources and revealed the chain propagation mechanisms of multi-dimensional risks. Furthermore, we constructed a three-level indicator system comprising 'Target Layer-Criterion Layer-Indicator Layer,' clarifying quantification methods and data sources. The study demonstrates that this system can provide a structured analytical tool for airspace management, route planning, and emergency response, facilitating the shift in low-altitude flight safety management from passive handling to proactive prevention and control. © 2025 IEEE.

Research on the Auxiliary Diagnosis Method of Parkinson's Disease Based on FMRI

Item Type Conference Paper**Author** M. Zuo**Author** M. Nie**Author** Q. Zhang

Abstract With the accelerating global aging population, the incidence of Parkinson's disease (PD) has been increasing annually, verwhelming families and society. However, traditional clinical diagnostic methods suffer from high subjectivity and elevated misdiagnosis rates. To address these challenges in PD diagnosis, this study proposes an enhanced Spatio-Temporal Linear Attention Transformer (STLAT) deep learning model based on the classical Transformer encoder. By extracting temporal and spatial features from resting-state functional magnetic resonance imaging (rs-fMRI), we introduce a multi-scale attention mechanism and an explainability quantification method to achieve accurate classification of PD patients and visualized diagnostic decision-making. Our approach constructs a standardized preprocessing pipeline to extract spatiotemporal features of brain regions and innovatively designs a spatiotemporal cross-attention module to capture dynamic functional connectivity patterns. Furthermore, we incorporate the integrated gradients saliency quantification (IG-SQ) method to interpret the decision rationale of the neural network. Experimentally, the method is proved to be correct up to 98.60% in PD binary classification. Through explainability

analysis, we successfully localize key pathological regions, including the basal ganglia and the default mode network (DMN). This study provides an explainable neuroimaging biomarker analysis framework for objective PD diagnosis and pathological mechanism research. © 2025 IEEE.

Abstract Quantum correlation shows a fascinating nature of quantum mechanics and plays an important role in some physics topics, especially in the field of quantum information. Quantum correlations of the composite system can be quantified by resorting to geometric or entropy methods, and all these quantification methods exhibit the peculiar freezing phenomenon. The challenge is to find the characteristics of the quantum states that generate the freezing phenomenon, rather than only study the conditions which generate this phenomenon under a certain quantum system. In essence, this is a classification problem. Machine learning has become an effective method for researchers to study classification and feature generation. In this work, we prove that the machine learning can solve the problem of X form quantum states, which is a problem of physical significance. Subsequently, we apply the density-based spatial clustering of applications with noise (DBSCAN) algorithm and the decision tree to divide quantum states into two different groups. Our goal is to classify the quantum correlations of quantum states into two classes: one is the quantum correlation with freezing phenomenon for both Rènyi discord ($\alpha = 2$) and the geometric discord (Bures distance), the other is the quantum correlation of non-freezing phenomenon. The results demonstrate that the machine learning method has reasonable performance in quantum correlation research. © 2020 Tech Science Press. All rights reserved.

Abstract Highlights: What are the main findings? A “spatiotemporal coupling” classification paradigm is proposed, which effectively mitigates the performance degradation in high-resolution remote sensing image classification caused by temporal differences through temporal segmentation and dedicated feature extractor strategies. A parcel-oriented deep texture feature extraction and quantification method is designed and implemented, transforming pixel-level features into statistically descriptive vectors with clear geographical significance, significantly enhancing feature discriminability and interpretability. What are the implications of the main findings? This framework provides a scalable solution for fine-grained land cover recognition using multi-temporal, high-resolution remote sensing imagery, particularly suitable for agricultural areas with significant seasonal surface cover variations. The proposed technical workflow of “feature extraction–entity constraint–statistical quantification” promotes the effective integration of deep learning models with Geographic Information System (GIS) management needs, offering practical reference value for real-world applications. High-spatial-resolution remote sensing imagery provides a data foundation for fine-grained land use classification. However, due to long revisit cycles and susceptibility to cloud cover, large-area imagery often suffers from temporal inconsistency, which severely limits the classification accuracy of traditional unified models. To address this issue, this study proposes a geographic entity-oriented, spatiotemporally coupled land use classification method for high-resolution remote sensing imagery, with agricultural land (including paddy fields, dry farmland and gardens) as an example for validation. In this method, the study area is first divided into multiple sub-regions based on image acquisition time, ensuring temporal consistency within each sub-region. A dedicated deep texture feature

extraction model is then constructed for each sub-region. This model is adapted from the advanced CAPTN texture recognition network: its classification head is removed, and a multi-scale feature fusion module is introduced, transforming it into an encoder focused on extracting spatial texture feature maps. Additionally, a self-supervised loss function combining masked feature reconstruction and cross-view consistency is designed to improve the quality of the learned texture features. During the prediction stage, the corresponding feature extractor is invoked based on the temporal phase of the imagery to generate a full-region texture feature map. This feature map is then cropped using land parcel vectors, and statistical feature vectors describing the texture attributes of each parcel are formed by calculating the mean and standard deviation of the features within each parcel. Finally, a Random Forest classifier is employed to determine the land parcel categories. This study uses the Jiangjin District of Chongqing City as the experimental area. The results show that, compared to training a unified deep learning model directly on full-region multi-temporal imagery or using traditional texture features, the proposed spatiotemporally coupled classification framework achieves significant improvements in overall accuracy and Kappa coefficient, reaching 92.3% and 0.89, respectively. © 2026 by the authors.

Abstract	Sulfur hexafluoride (SF6) is a high-quality ultra-high voltage insulating dielectric material with unique insulation and arc-extinguishing properties, and is widely used in power companies. However, sulfur hexafluoride is the strongest known greenhouse gas and is extremely difficult to degrade, so its emissions into the atmosphere need to be strictly limited. In the process of carbon emission reduction, the first step is to conduct carbon accounting, and accounting methods for SF6 emissions at home and abroad are gradually being supplemented and improved. Although major breakthroughs have been made in various aspects of SF6 carbon accounting at home and abroad, there is a lack of comprehensive discussion of the current main progress. This article first summarizes the current process of SF6 carbon accounting under two major categories and four methods at home and abroad. After that, the boundaries of each category, quantification methods, and accounting methods under the four major methods were further compared in detail. Finally, the positive impact that these methods can bring to the company's operations is analysed from the perspective of inventory reporting, certification application and domestic carbon market transaction profits. This article systematically explains the current research progress from the aspects of method classification, practical operation and final practical application, in order to provide theoretical support for further promoting new accounting methods in the future. © Published under licence by IOP Publishing Ltd.

Residential Energy Consumption Forecasting in Electric Utilities: An Approach Based on Random Forests and Time Series

Item Type Journal Article
Author J.L. Hernández
Author D. De Yong
Author F. Magnago
Author S. Bragnolo
Author J. Amaya

Abstract Forecasting the monthly electricity consumption of residential users is a critical task for improving energy planning, demand management, and the efficient integration of renewable energy sources into the electrical system. This study predicts the consumption of a single residential user based on historical data, including monthly consumption and average temperature records from November 2018 to December 2024. Five forecasting approaches are compared: moving averages, ARIMA, standard Random Forest, Random Forest with lag variables, and Random Forest with hyperparameter optimization using RandomizedSearchCV. The models performance is evaluated using MAE, MSE, and RMSE metrics over the last 12 months of the analyzed period, with 95% confidence intervals calculated via bootstrapping for both the validation phase and the estimation for January 2025. The results show that Random Forest models with lag variables and hyperparameter optimization outperform traditional methods such as moving averages and ARIMA in terms of accuracy. Additionally, the use of confidence intervals provides a more robust

assessment of prediction reliability. It is concluded that the combined use of machine learning techniques, selection of relevant historical variables, and uncertainty quantification methods offers an effective tool for anticipating residential electricity consumption behavior. This approach can be valuable for electric utilities and policymakers seeking datadriven, reliable, and reproducible decisions. © 2026 IEEE.

Resistant starch-enriched bread: Fibre content, analytical method comparison, and in-vitro digestibility effects

Item Type Journal Article

Author R. Sempio

Author L. Nyhan

Author E. Zannini

Author J. Walter

Author E.K. Arendt

Abstract Modern diets are often deficient in dietary fibre, increasing chronic disease risk. Reformulating staple foods like bread with resistant starch (RS) offers a practical solution. This study evaluated the partial replacement of flour with high concentration of RS-II, RS-III, RS-IV, and RS2-IV in bread, analysing their structural, nutritional, and digestibility impacts. Generally, breads enriched with RS showed a decrease in specific volume ranged between 32% and 42%, and an increase in hardness of up to 475%. Additionally, two fibre quantification methods were compared: AOAC 991.43 and AOAC 2017.16, as established by the AOAC (Association of Official Analytical Collaboration). All RS-enriched formulations met the “high in fibre” claim under AOAC 991.43, providing 17–31.5% of the daily fibre intake per 50 g portion versus 4.6% in the white control formulation. However, AOAC 2017.16 classified only RS-II and RS-III as “high in fibre,” while the two types of RS IV qualified as a “source of fibre”. Despite this, RS type IV showed the greatest reduction in reducing sugar release during in-vitro digestion (32% lower maltose release compared to the control), highlighting its potential to modulate postprandial glycaemic response. The study clarifies method-dependent fibre classification discrepancies and demonstrates RS-IV unique functional benefits compared to the other RS ingredients. These findings align with global reformulation policies, offering actionable strategies to enhance fibre intake through staple foods. Future research should focus on in-vivo studies and prioritise consumer acceptance and long-term health outcomes of RS-fortified products. © 2026 The Author(s).

Results of Approbation of the Method for Predicting the Classification Accuracy of Multichannel Images

Item Type Conference Paper

Author V. Lukin

Author I. Vasilyeva

Author B. Vozel

Abstract The results of verification of the method for predicting the classification accuracy for three-channel remote sensing images are presented. This study is carried out based on pixel-by-pixel classification according to the maximum likelihood criterion. As a criterion for classification accuracy, the weighted total probability of correct recognition of classes is taken, where the weight coefficients are a priori probabilities of the occurrence of objects from the corresponding classes. The results of comparison of statistical estimates of a priori probabilities of classes and their predictions by the Monte Carlo method using 'hard' and fuzzy classification are presented. Empirical dependences of the relative errors of prediction of the probabilities of correct recognition on the sample size are obtained. It is shown that predictions of the total probability of correct recognition, provided that the random sample is representative and of sufficient volume, produce the specified reliability. At the same time, the volume of processed data is significantly (at least by 1-2 orders of magnitude) reduced. This, in turn, leads to the corresponding reduction in the complexity of calculations and the time spent on obtaining predictions for the desired criteria. © 2022 IEEE.

RETHINKING CLASS-PRIOR ESTIMATION FOR POSITIVE-UNLABELED LEARNING

Item Type Conference Paper

Author Y. Yao

Author T. Liu

Author B. Han

Author M. Gong

Author G. Niu

Author M. Sugiyama

Author D. Tao

Abstract Given only positive (P) and unlabeled (U) data, PU learning can train a binary classifier without any negative data. It has two building blocks: PU class-prior estimation (CPE) and PU classification; the latter has been well studied while the former has received less attention. Hitherto, the distributional-assumption-free CPE methods rely on a critical assumption that the support of the positive data distribution cannot be contained in the support of the negative data distribution. If this is violated, those CPE methods will systematically overestimate the class prior; it is even worse that we cannot verify the assumption based on the data. In this paper, we rethink CPE for PU learning-can we remove the assumption to make CPE always valid? We show an affirmative answer by proposing Regrouping CPE (ReCPE) that builds an auxiliary probability distribution such that the support of the positive data distribution is never contained in the support of the negative data distribution. ReCPE can work with any CPE method by treating it as the base method. Theoretically, ReCPE does not affect its base if the assumption already holds for the original probability distribution; otherwise, it reduces the positive bias of its base. Empirically, ReCPE improves all state-of-the-art CPE methods on various datasets, implying that the assumption has indeed been violated here. © 2022 ICLR 2022 - 10th International Conference on Learning Representations. Abstract In this work, we propose a domain generalization (DG) approach to learn on several labeled source domains and transfer knowledge to a target domain that is inaccessible in training. Considering the inherent conditional and label shifts, we would expect the alignment of $p(x|y)$ and $p(y)$. However, the widely used domain invariant feature learning (IFL) methods relies on aligning the marginal concept shift w.r.t. $p(x)$, which rests on an unrealistic assumption that $p(y)$ is invariant across domains. We thereby propose a novel variational Bayesian inference framework to enforce the conditional distribution alignment w.r.t. $p(x|y)$ via the prior distribution matching in a latent space, which also takes the marginal label shift w.r.t. $p(y)$ into consideration with the posterior alignment. Extensive experiments on various benchmarks demonstrate that our framework is robust to the label shift and the cross-domain accuracy is significantly improved, thereby achieving superior performance over the conventional IFL counterparts. © 2021 International Joint Conferences on Artificial Intelligence. Revealing the built environment impacts of idling emissions from electric ride-hailing vehicles through explainable machine learning

Item Type Journal Article**Author** F. Lu**Author** S. Wang**Author** H. Bi

Abstract Understanding how built environment characteristics influence electric vehicles (EV) idling emissions is crucial for designing low-carbon transportation systems, yet this stationary emission source remains largely overlooked. This study fills this gap by integrating high-resolution GPS trajectory data, grid carbon intensity, and explainable machine learning to quantify the nonlinear impacts of the built environment on EV idling emissions. We developed a LightGBM-SHAP framework that achieves robust predictive performance ($R^2 = 0.889$) and systematically identified nonlinear thresholds. Three key findings emerged. First, across the seven observation days, lower daily mean temperatures were generally associated with higher estimated daily CO₂ emissions under the adopted temperature-dependent emission-accounting framework. Second, road network length, residential land, transportation facilities,

and population density collectively accounted for nearly 80% of total SHAP importance, with multiple built environment features exhibiting nonlinear threshold effects. Third, feature significance exhibited spatiotemporal heterogeneity, with identical built environment configurations exerting markedly different impacts across varying time periods and spatial scales. These findings should be interpreted as predictive associations rather than causal planning standards, offering diagnostic evidence for future policy evaluation. © 2026

Review and Performance Evaluation of Uncertainty Quantification in Data-Driven AI-Assisted Measurements

Item Type Journal Article

Author S. Shirmohammadi

Author F. Wang

Author C.-H. Hsu

Abstract As artificial intelligence (AI) becomes more prevalent in measurement systems and synthetic instruments, quantifying the uncertainty of AI-assisted measurements becomes a crucial and necessary part of the measurement process. In this article, we take a holistic approach toward both measurement science and AI's formulation and implementation of uncertainty, and we review and categorize data-driven AI-assisted uncertainty quantification methods with a novel taxonomy. We also provide a one-stop shop identifying AI literature practices that are noncompliant with measurement standards, allowing readers to spot such noncompliances and understand their practical impact. Furthermore, specifically for classification-assisted measurements, we test the most common epistemic Type A uncertainty quantification methods with 12 diverse datasets, and we evaluate their indirect measurement accuracy, one of the most important metrics for engineering applications, as well as precision, recall, and F1 score, each in both macro and weighted modes. Finally, we study the multiobservation variation of misclassification probability (MP) and experimentally show that in some cases it can be an indication of uncertainty: an interesting fact considering MP itself is not uncertainty. © 2022 IEEE.

Review on macropore flow in soil

Item Type Journal Article

Author Z.X. Gao

Author X.X. Xu

Author J.N. Zhao

Author C.P. Zhao

Author S.N. Zhang

Abstract Macropore flow is a natural and ubiquitous phenomenon in soil environment. Research on macropore flow involves studying mechanisms of soil water movement from homogeneous to heterogeneous fields, so it has become research focus in soil physical science. Understanding of mechanisms on macropore flow would provide useful information for irrigation, fertilization, crops planting and pollution tendency simulating. This paper introduces present research situation of macropore flow from classification standards, the influencing factors and quantitative methods, the deficiency of present research and research directions are discussed. The purpose of this paper is to provide some new ideas for deeply studying macropore flow.

Risk factor identification and nomogram-based predictive model development for recurrence of pituitary adenomas following transsphenoidal surgery: a dual-center retrospective study

Item Type Journal Article**Author** X. Yang**Author** W. Yang**Author** P. Hou**Author** Y. Chen**Author** J. Li**Author** J. Zhong**Author** S. Wang**Author** H. Chen

Abstract Objective – To identify independent risk factors for pituitary adenoma recurrence after transsphenoidal surgery and construct and validate a nomogram for recurrence risk quantification. Methods – We retrospectively collected clinical data of 469 patients with pituitary adenomas from Fuzhou 900 Hospital and Huashan Hospital of Fudan University. LASSO regression was applied to screen potential predictive factors, followed by multivariate Logistic regression to identify independent prognostic factors. Nomograms were subsequently constructed to evaluate the model's discriminative ability, calibration, and clinical utility. Results – Recurrence occurred in 64 cases (13.65%). Multivariate analysis confirmed modified Knosp classification (grades 3B–4), clival invasion, and subtotal resection as independent risk factors ($P < 0.05$). The model had AUC 0.905 [95%CI (0.8254, 0.9847)], C-index 0.905, sensitivity 85%, specificity 86.4%, with good calibration and clinical net benefits (DCA: 0.05–0.90 threshold). Conclusion – The nomogram, which is the first to integrate clival invasion with modified Knosp classification and extent of resection, effectively predicts pituitary adenoma recurrence after transsphenoidal surgery and shows promising clinical utility. © 2026 Yang, Yang, Hou, Chen, Li,

RISK QUANTIFICATION IN MANUFACTURING INDUSTRY INVESTMENTS: A STOCHASTIC APPROACH WITH ARTIFICIAL INTELLIGENCE

Item Type Journal Article

Author R.V. da Silva

Author E.M. Frazzon

Abstract Manufacturing investment decisions are often hindered by significant uncertainty. This paper introduces a conceptual model that integrates stochastic simulation with machine learning to quantify investment risk. Our hybrid approach employs a Monte Carlo simulation using time series data of fixed, variable, and investment costs as inputs. To enhance the simulation's realism, Long Short-Term Memory (LSTM) recurrent neural networks forecast the trend components of these series, while a Vector Autoregression (VAR) model captures their inter-correlations. This framework generates a multitude of potential scenarios, each evaluated through a mathematical model of the supply chain to produce a distinct cash flow. The subsequent application of investment metrics, such as Net Present Value (NPV) and Discounted Payback, to the distribution of these cash flows enables a comprehensive statistical analysis of the investment's risk profile, thereby providing robust support for strategic decision-

making. © 2025 by authors and Galileo Institute of Technology and Education of the Amazon (ITEGAM).

RiskTree: Decision trees for asset and process risk assessment quantification in big data platforms

Item Type Journal Article

Author H. Zhan

Author J. Yang

Author Z. Guo

Author J. Cao

Author D. Zhang

Author X. Zhao

Author W. You

Author H. Li

Abstract Currently, big data platforms are widely applied across various industries. These platforms are characterized by large scale, diverse forms, high update frequency, and rapid data flow, making it challenging to directly apply existing risk quantification methods to them. Additionally, the composition of big data platforms varies among enterprises due to factors such as industry, economic capability, and technical proficiency. To address this, we first developed a risk quantification assessment

process tailored to different types of big data platforms, taking into account relevant laws, regulations, and standards. Subsequently, we developed RiskTree, a risk quantification system for big data platforms, which supports automated detection of configuration files, traffic, and vulnerabilities. For situations where automated detection is not feasible or permitted, we provide a customized questionnaire system to collect assets and data processing procedures. We utilize a knowledge graph (KG) to integrate and analyze the collected data. Finally, we apply a random forest algorithm to compute risk index weights, risk values, and risk levels, enabling the quantification of risks on big data platforms. To validate the proposed process, we conducted experiments on an educational big data platform. The results demonstrate that the risk index system presented in this paper objectively and comprehensively reflects the risks faced by big data platforms. Furthermore, the proposed risk assessment process not only effectively identifies and quantifies risks but also provides highly interpretable evaluation results. © 2024 The Author(s).

RKHS bayes discriminant: A subspace constrained nonlinear feature projection for signal detection

Item Type Journal Article

Author U. Ozertem

Author D. Erdogmus

Abstract Given the knowledge of class probability densities, a priori probabilities, and relative risk levels, Bayes classifier provides the optimal minimum-risk decision rule. Specifically, focusing on the two-class (detection) scenario, under certain symmetry assumptions, matched filters provide optimal results for the detection problem. Noticing that the Bayes classifier is in fact a nonlinear projection of the feature vector to a single-dimensional statistic, in this paper, we develop a smooth nonlinear projection filter constrained to the estimated span of class conditional distributions as does the Bayes classifier. The nonlinear projection filter is designed in a reproducing kernel Hilbert space leading to an analytical solution both for the filter and the optimal threshold. The proposed approach is tested on typical detection problems, such as neural spike detection or automatic target detection in synthetic aperture radar (SAR) imagery. Results are compared with linear and kernel discriminant analysis, as well as classification algorithms such as support vector machine, AdaBoost and LogitBoost. © 2009 IEEE.

Abstract Despite the emergence of principled methods for domain adaptation under label shift, their sensitivity to shifts in class conditional distributions is precariously under explored. Meanwhile, popular deep domain adaptation heuristics tend to falter when faced with label proportions shifts. While several papers modify these heuristics in attempts to handle label proportions shifts, inconsistencies in evaluation standards, datasets, and baselines make it difficult to gauge the current best practices. In this paper, we introduce RLSBENCH, a large-scale benchmark for relaxed label shift, consisting of 500 distribution shift pairs spanning vision, tabular, and language modalities, with varying label proportions. Unlike existing benchmarks, which primarily focus on shifts in class-conditional $p(x|y)$, our benchmark also focuses on label marginal shifts. First, we assess 13 popular domain adaptation methods, demonstrating more widespread failures under label proportion shifts than were previously known. Next, we develop an effective two-step meta-algorithm that is compatible with most domain adaptation heuristics: (i) pseudo-balance the data at each epoch; and (ii) adjust the final classifier with target label distribution estimate. The meta-algorithm improves existing domain adaptation heuristics under large label proportion shifts, often by 2-10% accuracy points, while conferring minimal effect ($\sim 0.5\%$) when label proportions do not shift. We hope that these findings and the availability of RLSBENCH will encourage researchers to rigorously evaluate proposed methods in relaxed label shift settings. RNA-Seq Can Be Used to Quantify Gene Expression Levels for Use in the GARDskin Assay

Item Type Journal Article

Author R. Gradin

Author J. Andersson

Author A. Forreryd

Author H. Johansson

Abstract Non-animal methods for identification and characterization of skin sensitizers are continuously evolving, advancing towards more effective, accurate, and informational assays. The GARDskin assay is a scientifically and regulatory recognized assay for the assessment of skin sensitizers. It currently relies on targeted gene expression measurement to derive hazard classifications. With the progression of next generation sequencing technologies, whole transcriptome analysis provides an interesting alternative to the currently implemented targeted gene expression approach. RNA-seq was evaluated for its use in the GARDskin assay as a gene expression quantification method. Based on 24 paired samples acquired on both RNA-seq and the NanoString nCounter platform (the currently standard GARDskin acquisition method), gene expression profiles were found to be highly similar. Comparisons of treatment effects yielded a Spearman's correlation coefficient of 0.95 and a Lin's concordance correlation coefficient of 0.87. RNA-seq data was also used to classify the sensitizing hazard of 24 treatments using the standard GARDskin analysis pipeline. The classifications corresponded completely with references, rendering correct classifications for all treatments. In conclusion, it was found that the RNA-seq data strongly resembled NanoString nCounter data, and that it could be used to derive reliable hazard classifications in the GARDskin assay. © 2025 by the authors.

Robust and accurate quantification of biomarkers of immune cells in lung cancer micro-environment using deep convolutional neural networks

Item Type Journal Article

Author L. Aprupe

Author G. Litjens

Author T.J. Brinker

Author N. Grabe

Abstract Recent years have seen a growing awareness of the role the immune system plays in successful cancer treatment, especially in novel therapies like immunotherapy. The characterization of the immunological composition of tumors and their microenvironment is thus becoming a necessity. In this paper we introduce a deep learning-based immune cell detection and quantification method, which is based on supervised learning, i.e., the input data for training comprises labeled images. Our approach objectively deals with staining variation and staining artifacts in immunohistochemically stained lung cancer tissue and is as precise as humans. This is evidenced by the low cell count difference to humans of 0.033 cells on average. This method, which is based on convolutional neural networks, has the potential to provide a new quantitative basis for research on immunotherapy. © Copyright 2019 Aprupe et al.

Robust and scalable uncertainty estimation with conformal prediction for machine-learned interatomic potentials

Item Type Journal Article

Author Y. Hu

Author J. Musielewicz

Author Z.W. Ulissi

Author A.J. Medford

Abstract Uncertainty quantification (UQ) is important to machine learning (ML) force fields to assess the level of confidence during prediction, as ML models are not inherently physical and can therefore yield catastrophically incorrect predictions. Established a-posteriori UQ methods, including ensemble methods, the dropout method, the delta method, and various heuristic distance metrics, have limitations such as being computationally challenging for large models due to model re-training. In addition, the uncertainty estimates are often not rigorously calibrated. In this work, we propose combining the distribution-free UQ method, known as conformal prediction (CP), with the distances in the neural network's latent space to estimate the uncertainty of energies predicted by neural network force fields. We evaluate this method (CP+latent) along with other UQ methods on two essential aspects, calibration, and sharpness, and find this method to be both calibrated and sharp under the assumption of independent and identically-distributed (i.i.d.) data. We show that the method is relatively insensitive to hyperparameters selected, and test the limitations of the method when the i.i.d. assumption is violated. Finally, we demonstrate that this method can be readily applied to trained neural network force fields with traditional and graph neural network architectures to obtain estimates of uncertainty with low computational costs on a training dataset of 1 million images to showcase its scalability and portability. Incorporating the CP method with latent distances offers a calibrated, sharp and efficient strategy to estimate the uncertainty of neural network

force fields. In addition, the CP approach can also function as a promising strategy for calibrating uncertainty estimated by other approaches. © 2022 The Author(s). Published by IOP Publishing Ltd.

Robust Blood Cell Detection and Counting Using Efficient Channel Attention-Integrated YOLOv10

Item Type Conference Paper

Author R.R. Sohana

Author S. Ahmed

Author S.B. Shahid

Author R.H. Hridoy

Abstract Automated blood cell analysis plays a crucial role in early disease diagnosis. Traditional microscopic examination remains labor-intensive and prone to subjective variability. In this study, we have proposed an enhanced YOLOv10-

based detection framework integrated with Efficient Channel Attention (ECA) to classify and count red blood cells (RBCs), white blood cells (WBCs), and platelets from peripheral blood smear images. The ECA mechanism improves channel-wise feature selection without introducing computational overhead, enabling more accurate discrimination of morphologically similar cell types. Additionally, we have introduced an improved preprocessing pipeline, Contrast Limited Adaptive Histogram Equalization (CLAHE) that enhances local contrast in an image along with other techniques. The final model achieves an accuracy of approximately 97.00% across all classes, demonstrating superior robustness in both detection and categorization. These results highlight the potential of attention-enhanced lightweight architectures for clinical hematological analysis and pave the way for reliable and rapid diagnostic support. © 2025 IEEE.

Robust fine-grained echocardiographic view classification with supervised contrastive learning

Item Type Journal Article**Author** P. Naidoo**Author** P. Fernandes**Author** N. Dadashi Serej**Author** C.C. Stowell**Author** C.H. Manisty**Author** D.P. Francis**Author** M. Zolgharni

Abstract Accurate classification of echocardiographic views is fundamental for automated cardiac analysis. However, clinical practice relies on a large, heterogeneous set of fine-grained acquisitions that introduce substantial inter-observer variability. Existing studies have primarily focused on limited view sets, often collapsing specialised views into broad categories, which limits their clinical relevance. We address this limitation by introducing TTE47, the first publicly available benchmark comprising 47 clinically meaningful views annotated independently by three experts. This dataset enables the rigorous quantification of inter-observer agreement and establishes a foundation for reproducible, clinically relevant evaluation. To tackle the dual challenges of subtle inter-class distinctions and structured label variability, we propose a novel supervised contrastive learning framework incorporating a tailored loss function. Our method outperforms cross-entropy and standard supervised contrastive baselines, achieving leading performance among evaluated methods on TTE47 and surpassing prior work on TMED-2 without dataset-specific pretraining, using a model pretrained on TTE47. Beyond accuracy, we introduce clustering-based metrics, Detection Rate and Label Recovery Precision, that measure semantic coherence and the model's ability to resist annotation variability. Results show that the learned feature space aligns more strongly with underlying anatomical structure than with any single annotator's style, enabling resilience to label shifts and maintaining robustness comparable to human-level disagreement. By integrating multi-expert evaluation, robust representation learning, and interpretable feature-space analysis, this work establishes a scalable and clinically relevant framework for fine-grained echo view classification. Our findings highlight the potential of contrastive pretraining to standardise interpretation, mitigate subjectivity, and enhance the reliability of AI-assisted echocardiography in diverse clinical settings. © 2026 The Authors.

Abstract The label shift hypothesis posits that the source and target domains exhibit differing label priors while maintaining identical conditional probabilities. This core assumption enables models to adapt to domain distribution discrepancies through loss re-weighting or classifier output calibration, making it a prominent focus in open-environment machine learning. However, the prevalent existence of label noise severely degrades the classification efficacy of source classifiers, fundamentally undermining traditional label shift adaptation approaches. To address the dual challenges of label shift and label noise, we propose the Denoising Expectation-Maximization (DNEM) framework, which enhances model robustness against distribution shifts and label noise via iterative estimation of noise transition matrices and optimization of importance weights.

Leveraging the memorization effect in deep learning, DNEM dynamically adjusts the learning rate for noise matrix estimation, maintaining conservative updates during initial training phases to preserve knowledge from relatively clean labels. Extensive experiments on multiple benchmark datasets demonstrate that DNEM consistently outperforms state-of-the-art methods under high noise rates and diverse shift conditions. © The Author(s), under exclusive license to Springer Nature Singapore Pte Ltd. 2026.

Robust model selection for positive and unlabeled learning with constraints

Item Type Journal Article

Author T. Wei

Author H. Wang

Author W. Tu

Author Y. Li

Abstract Positive and unlabeled (PU) learning is the problem in which training data contains only PU samples. Although PU learning is widely used in real-world applications, its model selection remains challenging. Specifically, traditional model selection methods are often highly sensitive to the class prior as well as the data size, resulting in human overhead in hyperparameter optimization. In this paper, we present a method called ODE (robust model selection) for robust model selection in PU learning. Two novel model evaluators based on the integral probability metric and area under the curve, which are free of the class prior, are introduced, and a variance reduction method is further employed to improve the quality of model selection. In addition, we perform model selection under user-defined constraints and propose a fast halving-style searching algorithm to efficiently identify the most promising model configuration. Extensive empirical studies demonstrate that our proposed method performs more robustly and is more computationally efficient than many state-of-the-art methods. © 2022, Science China Press and Springer-Verlag GmbH Germany, part of Springer Nature.

Robust multi-class transductive learning with graphs

Item Type Conference Paper

Author W. Liu

Author S.-F. Chang

Abstract Graph-based methods form a main category of semisupervised learning, offering flexibility and easy implementation in many applications. However, the performance of these methods is often sensitive to the construction of a neighborhood graph, which is non-trivial for many realworld problems. In this paper, we propose a novel framework that builds on learning the graph given labeled and unlabeled data. The paper has two major contributions. Firstly, we use a nonparametric algorithm to learn the entire adjacency matrix of a symmetry-favored k-NN graph, assuming that the matrix is doubly stochastic. The nonparametric algorithm makes the constructed graph highly robust to noisy samples and capable of approximating underlying submanifolds or clusters. Secondly, to address multi-class semi-supervised classification, we formulate a constrained label propagation problem on the learned graph by incorporating class priors, leading to a simple closed-form solution. Experimental results on both synthetic and real-world datasets show that our approach is significantly better than the state-of-the-art graph-based semi-supervised learning algorithms in terms of accuracy and robustness. ©2009 IEEE.

Abstract Objective: Homogeneity is a notion used to describe images in various fields and is often linked to critical aspects of those fields. However, this term is rarely defined in the literature and no gold standard exists for its quantification. A few quantification algorithms have been proposed, but they lack both simplicity and robustness. As a result, the scientific community uses the notion of homogeneity in subjective analysis, preventing objective comparison of a large number of data or of different studies. The main objectives of this manuscript are to propose a definition of homogeneity and an algorithm for its quantification. Method: This algorithm, called MASQH, rely on a multi-scale, statistical and segmentation-free approach and outputs a single homogeneity index, which makes it robust and easy to use. Results: The performance and reliability of the method are demonstrated through three case studies: Firstly, on synthetic images to study the behavior and assess the relevance of the algorithm in diverse situations and hence, in various potential fields. Secondly, on histological images derived from experimental chitosan-platelet-rich-plasma hybrid biomaterial, where the quantitative results are compared to a qualitative classification provided by an expert in the field. Thirdly, on experimental nanocomposites images for which results are compared to two other homogeneity quantification algorithms from the field of nanocomposites. Conclusion and significance: By quantifying homogeneity, the MASQH method may help to compare disparate studies in the literature and quantitatively demonstrate the impact of homogeneity in various fields. The MASQH method is freely available online. © 1992-2012 IEEE.

Abstract Many studies have shown that non-default decision thresholds are required to maximize classification performance on highly imbalanced data sets. Thresholding strategies include using a threshold equal to the prior probability of the positive class or identifying an optimal threshold on training data. It is not clear, however, how these thresholding strategies will generalize to imbalanced data sets that contain class label noise. When class noise is present, the positive class prior is influenced by the class label noise, and a threshold that is optimized on noisy training data may not generalize to test data. We employ four thresholding strategies: two thresholds that are optimized on training data and two thresholds that depend on the positive class prior. Threshold strategies are evaluated on a range of noise levels and noise distributions using the Random Forest, Multilayer Perceptron, and XGBoost learners. While all four thresholding strategies significantly outperform the default threshold with respect to the Geometric Mean (G-Mean), three of the four thresholds yield unstable true positive rates (TPR) and true negative rates (TNR) in the presence of class noise. Results show that setting the threshold equal to the prior probability of the noisy positive class consistently performs best according to G-Mean, TPR, and TNR.

This is the first evaluation of thresholding strategies for imbalanced and noisy data, to the best of our knowledge, and our results contradict related works that have suggested optimizing thresholds on training data as the best approach. © 2021 IEEE.

Robust Uncertainty Quantification Using Conformalised Monte Carlo Prediction

Item Type Conference Paper

Author D. Bethell

Author S. Gerasimou

Author R. Calinescu

Editor Wooldridge M.

Editor Dy J.

Editor Natarajan S.

Abstract Deploying deep learning models in safety-critical applications remains a very challenging task, mandating the provision of assurances for the dependable operation of these models. Uncertainty quantification (UQ) methods estimate the model's confidence per prediction, informing decision-making by considering the effect of randomness and model misspecification. Despite the advances of state-of-the-art UQ methods, they are computationally expensive or produce conservative prediction sets/intervals. We introduce MC-CP, a novel hybrid UQ method that combines a new adaptive Monte Carlo (MC) dropout method with conformal prediction (CP). MC-CP adaptively modulates the traditional MC dropout at runtime to save memory and computation resources, enabling predictions to be consumed by CP, yielding robust prediction sets/intervals. Throughout comprehensive experiments, we show that MC-CP delivers significant improvements over comparable UQ methods, like MC dropout, RAPS and CQR, both in classification and regression benchmarks. MC-CP can be easily added to existing models, making its deployment simple. The MC-CP code and replication package is available at <https://github.com/team-daniel/MC-CP>. Abstract It is important to estimate the performance gap of a given deep learning model on the target data set, since discrepancy or bias between source and target domains is a common and fundamental problem in the practice of machine learning techniques. Without any assumptions on data bias, such as label shift or covariate shift and without target data labels, we propose a robustness estimation method based on prediction consistency evaluation between source and target data in the neighborhood of the source samples. Considering outliers and whether the user provided model is fully trained, a variety of variant methods are also tried, including setting neighborhood threshold to average intra-class distance for each category and relative robustness. Furthermore, the time complexity of this method is $O(n \log n)$, which is applicable for large datasets. Experiments on the handwritten digit recognition and Japanese handwriting recognition show that the proposed methods are effective. © 2019 IEEE.

ROC analysis with multiple classes and multiple tests: Methodology and its application in microarray studies

Item Type Journal Article

Author J. Li

Author J.P. Fine

Abstract The accuracy of a single diagnostic test for binary outcome can be summarized by the area under the receiver operating characteristic (ROC) curve. Volume under the surface and hypervolume under the manifold have been proposed as extensions for multiple class diagnosis (Scurfield, 1996, 1998). However, the lack of simple inferential procedures for such measures has limited their practical utility. Part of the difficulty is that calculating such quantities may not be straightforward, even with a single test. The decision rule used to generate the ROC surface requires class probability assessments, which are not provided by the tests. We develop a method based on estimating the probabilities via some procedure, for example, multinomial logistic regression. Bootstrap inferences are proposed to account for variability in estimating the probabilities and perform well in simulations. The ROC measures are compared to the correct classification rate, which depends heavily on class prevalences. An example of tumor classification with microarray data demonstrates that this property may lead to substantially different analyses. The ROC-based analysis yields notable decreases in model complexity over previous analyses. © The Author 2008. Published by Oxford University Press. All rights reserved.

Abstract Assessing the impact of garbage classification on air pollution in rapidly developing economic regions is particularly necessary in light of the current policy trends. We evaluated the resulting changes in air pollution levels before and after garbage classification based on a three-year field observation using high-resolution online instruments in a municipal solid waste comprehensive disposal base. A targeted scheme is proposed to analyze the variation characteristics of major sources in a complex multi-source environment (Environments with multiple sources of pollution). We found that the concentrations of hydrogen sulfide (H₂S) and volatile organic compounds (VOCs) in ambient air decreased by 48% and 43% respectively after garbage classification, and their spike frequency was controlled at approximately 0.01. The average H₂S and VOC concentrations were generally low during the daytime, but relatively high during the nighttime because of meteorology and photochemistry. The ozone formation potential of the base decreased by 56%. Alternatively, emissions from transportation and combustion sources increased, while landfill pollution decreased owing to changes in the method of waste disposal. This finding suggests that garbage classification is an effective means of improving the air quality. This new scheme has a good potential in actual research scenarios. © 2023

Abstract Protonic ceramic electrochemical cells (PCECs) offer promising paths for energy storage and conversion. Despite considerable achievements made, PCECs still face challenges such as physiochemical compatibility between components and suboptimal solid–solid contact at the interfaces between the electrolytes and electrodes. In this study, a novel approach is proposed that combines in situ electrochemical characterization of interfacial electrical sensor embedded PCECs and machine learning to quantify the contributions of different cell components to total degradation, as well as to predict the remaining useful life. The experimental results suggest that the overpotential induced by the oxygen electrode is 48% less than that of oxygen electrode/electrolyte interfacial contact for up to 1171 h. The data-driven machine learning simulation predicts the RUL of up to 2132 h. The root cause of degradation is overpotential increase induced by oxygen electrode, which accounts for 82.9% of total cell degradation. The success of the failure diagnostic model is demonstrated by its consistency with degradation modes that do not manifest in electrolysis fade during early real operations. This synergistic approach provides valuable insights into practical failure diagnosis of PCECs and has the potential to revolutionize their development by enabling improved performance prediction and material selection for enhanced durability and efficiency. © 2023 The Authors. Author A. Marathe

Author S. Roy

Author D. Singh

Author R. Walambe

Author K. Kotecha

Abstract This paper describes a self supervised representation learning approach that can perform robust object detection in out-of-distribution rotated images for autonomous driving task. Keeping in mind the limitations of vehicle sensors we incorporate self-supervised rotation invariance for correcting rotational corruptions. We present a comprehensive analysis of observed label shifts, validate the results using holdout sets and provide explainability for the

performance using GradCAM approach. We demonstrate results on real-world adversarial examples: (Autonomous Scenes - DAWN dataset) that significantly outperform common methods. The proposed framework outperforms the rotation-affected benchmark by 14.73 points of mAP for the OD task in autonomous driving applications. ©2024 IEEE.

S2MetNet: A novel dataset and deep learning benchmark for methane point source quantification using Sentinel-2 satellite imagery

Item Type Journal Article

Author A. Radman

Author M. Mahdianpari

Author D.J. Varon

Author F. Mohammadimanesh

Abstract Methane, as a crucial greenhouse gas, plays a significant role in global warming, contributing to approximately one-quarter of the observed climate change since pre-industrial times. Consequently, the detection and quantification of major methane emitters are vital in addressing this issue effectively. Satellite sensors with shortwave infrared (SWIR) spectral bands provide valuable information for monitoring methane emissions. For example, Sentinel-2 multispectral data have the capability to detect methane plumes of large point sources. As such, a wide range of quantification approaches have been developed to quantify methane source rates based on this dataset. Most of the existing methods, however, require auxiliary data, such as wind speed, and have large uncertainties. In this study, we introduce a novel approach based on deep learning models to enhance the precision of methane quantification using Sentinel-2 data without the reliance on external data sources. To train the proposed deep learning model, a comprehensive benchmark dataset has been generated, using Sentinel-2 data. This dataset is created by integrating simulated plumes and background noise extracted from real Sentinel-2 images. This approach ensures the integration of realistic environmental conditions within the simulated data, enhancing the robustness and reliability of our proposed model. The generated benchmark dataset is utilized in different deep learning architectures, namely VGG-19, ResNet-50, Inception-v3, DenseNet-121, Swin-T, and EfficientNet-V2L, to estimate methane source rate. The performance of deep models has been evaluated in three learning strategies, namely from scratch, transfer-learning, and fine-tuning. The fine-tuned EfficientNet-V2L achieves the highest accuracy with root-mean-square error (RMSE), mean absolute percentage error (MAPE), and Pearson R of 2101 kg h⁻¹, 10.05%, and 95.70%, respectively. More importantly, the proposed model demonstrates superior performance compared to conventional physical-based quantification methods (e.g., integrated mass enhancement) and recently developed deep learning model techniques (e.g., MethaNet). In particular, the proposed model exhibits an improvement of approximately 1287 kg h⁻¹ in terms of RMSE, a 3.92% reduction in MAPE, and a 5.01% enhancement in R compared to the IME method. These results highlight the advancements achieved by the proposed approach in accurately quantifying methane emissions using Sentinel-2 imagery. The generated benchmark dataset and the developed deep learning model presented in this study serve as a fundamental resource and constructive framework for future research, promoting extensive implementation across various methane monitoring scenarios on different satellites and in distinct geographic regions, which delivering greater effectiveness to global methane emission monitoring initiatives. © 2023 Elsevier Inc.

Safety assessment of basiliximab using real-world adverse event data from the FDA Adverse Event Reporting System Database: A retrospective observational study

Item Type Journal Article

Author S. Chen

Author X. Ma

Author J. Zhang

Abstract This study analyzed adverse drug events (ADEs) associated with basiliximab, sourced from the Food and Drug Administration Adverse Event Reporting System (FAERS) database, spanning the first quarter of 2004 to the fourth quarter of 2023. We collected ADE data for basiliximab from 2004 Q1 to 2023 Q4. After standardization, we employed several signal quantification methods for analysis, such as the Reporting Odds Ratio (ROR), Proportional Reporting Ratio (PRR), Bayesian Confidence Propensity for Neural Networks (BCPNN), and empirical bayes geometric mean (EBGM). In this analysis of 1520 ADEs reports citing basiliximab as the primary suspect, we identified 295 preferred terms across 24 system organ classifications (SOCs). The 3 most prevalent SOCs were investigated (n = 1403, ROR 2.84, PRR 2.54, IC 1.34, EBGM 2.54), infections and infestations (n = 1198, ROR 2.85, PRR 2.59, IC 1.37, EBGM 2.59), and renal and urinary disorders (n = 903, ROR 6.01, PRR 5.48, IC 2.45, EBGM 5.47). Increased blood creatinine and pyrexia were the most frequently reported adverse events (AEs) associated with basiliximab, and cytomegalovirus infection also demonstrated significant signal intensity. Notably, this study revealed some adverse reactions beyond basiliximab drug instructions, such as mitral valve calcification, diastolic dysfunction, pelvic fluid collection, testicular swelling, soft tissue necrosis, and muscle necrosis. Although basiliximab offers therapeutic benefits, it carries the risk of several adverse reactions. Clinicians should monitor patients for signs of increased serum creatinine level, fever, cytomegalovirus infection, anaphylactic shock, mitral valve calcification, diastolic

dysfunction, pelvic fluid collection, testicular swelling, soft tissue necrosis, muscle necrosis, and other events during clinical use. © 2024 Lippincott Williams and Wilkins. All rights reserved.

Safety Certificate against Latent Variables with Partially Unidentifiable Dynamics

Item Type	Conference Paper

Abstract	Existing control techniques often assume access to complete dynamics or perfect simulators with fully observable states, which are necessary to verify whether the system remains within a safe set (forward invariance) or safe actions are persistently feasible at all times. However, many systems contain latent variables that make their dynamics partially unidentifiable or cause distribution shifts in the observed statistics between offline and online data, even when the underlying mechanistic dynamics are unchanged. Such “spurious” distribution shifts can break many techniques that use data to learn system models or safety certificates. To address this limitation, we propose a technique for designing probabilistic safety certificates for systems with latent variables. A key technical enabler is the formulation of invariance conditions in probability space, which can be constructed using observed statistics in the presence of distribution shifts due to latent variables. We use this invariance condition to construct a safety certificate that can be implemented efficiently in real-time control. The proposed safety

certificate can persistently find feasible actions that control long-term risk to stay within tolerance. Stochastic safe control and (causal) reinforcement learning have been studied in isolation until now. To the best of our knowledge, the proposed work is the first to use causal reinforcement learning to quantify long-term risk for the design of safety certificates. This integration enables safety certificates to efficiently ensure longterm safety in the presence of latent variables. The effectiveness of the proposed safety certificate is demonstrated in numerical simulations. © 2025, ML Research Press. All rights reserved.

Sag Measurement and Quantification in Transmission Lines: A Review

Item Type Conference Paper

Author S.P. Rao

Author F. Rahman

Author P. Ranganathan

Abstract Sags are a serious issue and play a critical role for its cause due to multiple environmental factors such as extreme weather events: wind speed, blizzard, and heat loss. This paper provides a comprehensive review of sag measurements and its quantification methods. Current sag measurement and monitoring approaches are quantified using optical sensors, phasor measurement units, image processing techniques, smart grid technologies, and machine learning algorithms. The paper also proposes a futuristic sag measuring system that is hierarchical and categorized into a sensing, communication, control, and storage levels irrespective of the deployed sensing technology. © 2024 IEEE.

Abstract SAINT (Significance Analysis of INteractome) is a probabilistic method for scoring bait-prey interactions against negative controls in affinity purification – mass spectrometry (AP-MS) experiments. Our published SAINT algorithms use spectral counts or protein intensities as the input for calculating the probability of true interaction, which enables objective selection of high-confidence interactions with false discovery control. With the advent of new protein quantification methods such as Data Independent Acquisition (DIA), we redeveloped the scoring method to utilize the reproducibility information embedded in the peptide or fragment intensity data as a key scoring criterion, bypassing protein intensity summarization required in the previous SAINT workflow. The new software package, SAINTq, addresses key issues in the interaction scoring based on intensity data, including treatment of missing values and selection of peptides and fragments for scoring each prey protein. We applied SAINTq to two independent DIA AP-MS data sets profiling the interactome of MEPCE and EIF4A2 and that of 14-3-3 β , and benchmarked the performance in terms of recovering previously reported literature interactions in the iRefIndex database. In both data sets, the SAINTq analysis using the fragment-level intensity data led to the most sensitive detection of literature interactions at the same level of specificity. This analysis outperforms the analysis using protein intensity data summed from fragment intensity data that is equivalent to the model in SAINTexpress. © 2016 WILEY-VCH Verlag GmbH & Co. Sample pooling approaches simulated under resource scarcity, lapses in testing capacity, and rapid processing demands for surveillance testing: a data-driven performance comparison

Item Type Journal Article

Abstract Background: Sample pooling is a critical strategy to meet increased testing demand and conserve resources in surveillance testing. Much of its effectiveness depends on how well optimized the pool size is to the prevalence of infection in the sampled population, which can be difficult to anticipate in many circumstances. Multiple methods exist to better optimize pooling, with unique trade-offs. Methods: Pooling optimization methods were simulated to examine trade-offs between surveillance priorities and operational characteristics using SARS-CoV-2 surveillance data and workflows generated by the Virginia Tech Molecular Diagnostics Laboratory under varying capacity conditions. All in-house validation procedures were designed and established exclusively under CLIA to ensure full control of the analytical framework and to accurately reflect true capacity constraints. We used binary surveillance data to run Monte Carlo simulations (MCS) comparing conservative and large fixed pools, historical prevalence optimization (HPO), prevalence estimation testing (PET), truly optimized pooling, and individual testing. Median test counts from the MCS fed a discrete-event simulation (DES) that assessed processing time at different lab capacities under surveillance and outbreak conditions. We then used the combined performance results to build a classification tree to guide method selection under

different testing priorities and constraints. Results: MCS results indicated that small pools (4 samples), HPO, and PET resulted in test counts that were not statistically different from truly optimized pooling ($p > 0.05$). The DES showed that pooling methods generally performed comparably to individual testing in processing time at low laboratory capacity, but individual testing became faster as capacity increased. Across capacity conditions, individual testing processed fewer than 500 daily samples more quickly, yet it demanded more hands-on time than pooling. Large-scale surveillance favored pooled methods, which were quicker under most conditions, while outbreak scenarios often favored individual testing when capacity wasn't highly limited. Machine learning analysis highlighted surveillance priorities and sample intake as key determinants in selecting the best pooling optimization method for the given circumstance. Conclusion: This study demonstrates the importance of maintaining multiple pooling optimization approaches and adapting strategies to match evolving demands and potential constraints in surveillance testing. Clinical trial number: Not applicable. © The Author(s) 2025.

Abstract Development of an accurate, flexible, and numerically efficient uncertainty quantification (UQ) method is one of fundamental challenges in machine learning. Previously, a UQ method called DISCO Nets has been proposed (Bouchacourt et al., 2016) that trains a neural network by minimizing the so-called energy score on training data. This method has shown superior performance on a hand pose estimation task in computer vision, but it remained unclear whether this method works as nicely for regression on tabular data, and how it competes with more recent advanced UQ methods such as NGBoost. In this paper, we propose an improved neural architecture of DISCO Nets that admits a more stable and smooth training. We benchmark this approach on miscellaneous real-world tabular datasets and confirm that it is competitive with or even superior to standard UQ baselines. We also provide a new elementary proof for the validity of using the energy score to learn predictive distributions. Further, we point out that DISCO Nets in its original form ignore epistemic uncertainty and only capture aleatoric uncertainty. We propose a simple fix to this problem. Satellite-Derived Approaches for Coal Mine Methane Estimation: A Review

Item Type Journal Article

Author A. Chauhan

Author S. Raval

Abstract Highlights: What are the main findings? Satellite observations have advanced from coarse (~10 km) to fine (25 m) resolution, greatly improving plume detection and narrowing gaps between bottom-up and top-down methane estimates. Significant uncertainties persist due to wind variability, terrain heterogeneity, retrieval-algorithm limitations, and limited temporal sampling, leading to inconsistent quantification, especially for diffuse surface coal-mine emissions. What are the implications of the main findings? Reliable site-level methane estimates require integrating satellites with ground and aerial validation, improved atmospheric modelling, and machine-learning methods that address diffuse and variable coal mine emissions. Reducing these uncertainties is essential for accurate reporting and effective mitigation in coal mining regions, thereby strengthening global climate action. Methane emissions from coal mines, especially surface operations, are spatially diffuse, presenting significant challenges for accurate quantification. Satellites such as TROPOMI, GHGSat, PRISMA, GaoFen-5, and GOSAT have been extensively used for detecting methane emissions at various scales, from individual point sources to regional and global assessments. Despite various advancements, methane quantification via satellite observations remains subject to several challenges. Various quantification methods for the same observation can produce variable results. Also, meteorological conditions, terrain complexity, and surface heterogeneity introduce uncertainties in emission estimates. The selection of wind speed and direction, along with retrieval-algorithm limitations, can lead to significant discrepancies in reported emissions. Additionally, satellite-based observations capture emissions only at specific overpass times, which may introduce temporal uncertainties compared to inventories derived from continuous emission estimations. This study provides a comprehensive review of satellite-based coal mine methane (CMM) monitoring, evaluating current methodologies, their limitations, and recent technological advancements. We discussed the potential of emerging machine-learning techniques, improved atmospheric modelling, and integrated observational approaches to enhance methane emission quantification. By refining satellite-based monitoring techniques and addressing existing challenges, this research will support the development of more accurate emission inventories and effective mitigation strategies for the coal mining sector. © 2025 by the authors.

SC-JNMF: Single-cell clustering integrating multiple quantification methods based on joint non-negative matrix factorization

Item Type Journal Article

Author M. Shiga

Author S. Seno

Author M. Onizuka

Author H. Matsuda

Abstract Single-cell RNA-sequencing is a rapidly evolving technology that enables us to understand biological processes at unprecedented resolution. Single-cell expression analysis requires a complex data processing pipeline, and the pipeline is divided into two main parts: The quantification part, which converts the sequence information into gene-cell matrix data; the analysis part, which analyzes the matrix data using statistics and/or machine learning techniques. In the analysis part, unsupervised cell clustering plays an important role in identifying cell types and discovering cell diversity and subpopulations. Identified cell clusters are also used for subsequent analysis, such as finding differentially expressed genes and inferring cell trajectories. However, single-cell clustering using gene expression profiles shows different results depending on the quantification methods. Clustering results are greatly affected by the quantification method used in the upstream process. In other words, even if the original RNA-sequence data is the same, gene expression profiles processed by different quantification methods will produce different clusters. In this article, we propose a robust and highly accurate clustering method based on joint non-negative matrix factorization (joint-NMF) by utilizing the information from multiple gene expression profiles quantified using different methods from the same RNA-sequence data. Our joint-NMF can extract common factors among multiple gene expression profiles by applying each NMF under the constraint that one of the factorized matrices is shared among multiple NMFs. The joint-NMF determines more robust and accurate cell clustering results by leveraging multiple quantification methods compared to conventional clustering methods, which use only a single gene expression profile. Additionally, we showed the usefulness of discovering marker genes with the extracted features using our method. Copyright © 2021 Shiga et al.

Scalability of continuous active learning for reliable high-recall text classification

Item Type Conference Paper**Author** G.V. Cormack**Author** M.R. Grossman

Abstract For finite document collections, continuous active learning ("CAL") has been observed to achieve high recall with high probability, at a labeling cost asymptotically proportional to the number of relevant documents. As the size of the collection increases, the number of relevant documents typically increases as well, thereby limiting the applicability of CAL to low-prevalence high-stakes classes, such as evidence in legal proceedings, or security threats, where human effort proportional to the number of relevant documents is justified. We present a scalable version of CAL ("S-CAL") that requires $O(\log N)$ labeling effort and $O(N \log N)$ computational effort - where N is the number of unlabeled training examples - to construct a classifier whose effectiveness for a given labeling cost compares favorably with previously reported methods. At the same time, S-CAL offers calibrated estimates of class prevalence, recall, and precision, facilitating both threshold setting and determination of the adequacy of the classifier. © 2016 Copyright held by the owner/author(s).

Abstract Quantifying the importance of each training point to a learning task is a fundamental problem in machine learning and the estimated importance scores have been leveraged to guide a range of data workflows such as data summarization and domain adaption. One simple idea is to use the leave-one-out error of each training point to indicate its importance. Recent work has also proposed to use the Shapley value, as it defines a unique value distribution scheme that satisfies a set of appealing properties. However, calculating Shapley values is often expensive, which limits its applicability in real-world applications at scale. Multiple heuristics to improve the scalability of calculating Shapley values have been proposed recently, with the potential risk of compromising their utility in real-world applications. How well do existing data quantification methods perform on existing workflows? How do these methods compare with each other, empirically and theoretically? Must we sacrifice scalability for the utility in these workflows when using these methods? In this paper, we conduct a novel theoretical analysis comparing the utility of different importance quantification methods, and report extensive experimental studies on existing and proposed workflows such as noisy label detection, watermark removal, data summarization, data acquisition, and domain adaptation. We show that Shapley value approximation based on a KNN surrogate over pretrained feature embeddings obtains comparable utility with existing algorithms while achieving significant scalability improvement, often by orders of magnitude. Our theoretical analysis also justifies its advantage over the leave-one-out error. The code is available at <https://github.com/AIsecure/Shapley-Study>. © 2021 IEEE

Abstract Recent years have witnessed an upsurge of interest in employing flexible machine learning models for instrumental variable (IV) regression, but the development of uncertainty quantification methodology is still lacking. In this work we present a scalable quasi-Bayesian procedure for IV regression, building upon the recently developed kernelized IV models. Contrary to Bayesian modeling for IV, our approach does not require additional assumptions on the data generating process, and leads to a scalable approximate inference algorithm with time cost comparable to the corresponding point estimation methods. Our algorithm can be further extended to work with neural network models. We analyze the theoretical properties of the proposed quasi-posterior, and demonstrate through empirical evaluation the competitive performance of our method. © 2021 Neural information processing systems foundation. Scale-Dependent hydroxyl radical generation and energy efficiency in vortex diode hydrodynamic cavitation: machine learning insights toward industrial-scale applications in water treatment

Item Type Journal Article**Author** X. Pang**Author** V.P. Sarvothaman**Author** S.R. Kulkarni**Author** W.L. Roberts**Author** V.V. Ranade

Abstract Hydrodynamic cavitation (HC) reactors are increasingly applied in the remediation of organic pollutants in water, leveraging intense shear and hydroxyl radical ($\text{OH}\cdot$) generation to accelerate degradation processes. However, scaling up HC devices remains a challenge in environmental engineering due to poorly understood effects at different scales of operation. Vortex-based HC (VDs) provide superior cavitation efficiency compared to traditional orifice and venturi devices and therefore this study examines the scale-dependent generation of $\text{OH}\cdot$ in VDs. Coumarin dosimetry was employed as the quantification method for $\text{OH}\cdot$ generation. Available published experimental datasets were analysed: (i) varying inlet pressures from 100 to 400 kPa for throat diameters of 6 and 12 mm, and (ii) throat diameters ranging from 6 to 38 mm (nominal capacities of 5 to 200 L/min) at a fixed pressure drop of 280 kPa. After normalization of the available data, seven machine learning (ML) models were trained to establish relationships between operating conditions and $\text{OH}\cdot$ generation

performance. eXtreme Gradient Boosting (XGB) and artificial neural networks (ANN) outperformed the others, with higher R² and lower RMSE. After using SHAP interpretation, these two models were used to elucidate scale effects on both radical yield and energy efficiency, resulting in actionable design guidelines for VDs at different scales. By combining experimental dosimetry with predictive ML, this work advances the fundamental understanding and practical implementation of cavitation-based advanced oxidation technologies, particularly for efficient and energy-optimized treatment of organic pollutants in wastewater. © 2026 The Authors

Scaling Smart Cities with Federated Learning: Balancing Accuracy and Privacy for Building Energy Performance Prediction

Item Type Journal Article**Author** J. Delgado Fernández**Author** L. Willburger**Author** C. Wiethe**Author** S. Wenninger**Author** G. Fridgen

Abstract The building energy sector is a significant contributor to carbon emissions, thereby playing a crucial role in driving global sustainability efforts to achieve the net-zero targets outlined in the Paris Climate Agreement. Precise predictions of building energy performance are imperative for effective planning and investment decisions aimed at enhancing energy efficiency. While data-driven methods, primarily leveraging machine learning techniques, offer promising predictive capabilities, they heavily rely on large datasets for accurate assessments. However, a prevalent challenge arises as energy consultants and agencies often lack expansive datasets, and if they do, they are reluctant to share their data. To overcome these hurdles, the study implements a decentralized, privacy-preserving machine learning approach known as federated learning. This approach was applied to a dataset encompassing over 25,000 residential buildings featuring diverse construction attributes and energy sources. The simulation involved mimicking different energy agencies by segmenting geographic regions. The study compared the prediction performance of federated learning with that of a model accessing the entire dataset and a fully isolated local model. The findings demonstrate that federated learning achieves a 12% improvement in prediction performance compared to the isolated model. This outcome underscores federated learning's capacity to leverage the full potential of scaling data-driven methodologies, providing a pathway to unlock new business models in both research and practice, while aligning with net-zero aspirations. © The Author(s) 2025.

Screening mammography beyond breast cancer: breast arterial calcifications as a sex-specific biomarker of cardiovascular risk

Item Type Journal Article

Author R.M. Trimboli

Author M. Codari

Author M. Guazzi

Author F. Sardanelli

Abstract Purpose: To highlight the importance of quantitative breast arterial calcifications (BAC) assessment for an effective stratification of cardiovascular (CV) risk in women, for whom current preventive strategies are inadequate. BAC, easily detectable on mammograms, are associated with CV disease and represent a potential imaging biomarker for CV disease prevention in women. Method: We summarized the available evidence on this topic. Results: Age, parity, diabetes, and hyperlipidemia were found to positively correlate with BAC. Women with BAC have a higher CV risk than those without BAC: the relative risk was reported to be 1.4 for transient ischemic attack/stroke, 1.5 for thrombosis, 1.8 for myocardial infarction; the reported hazard ratio was 1.32 for coronary artery disease (CAD), 1.52 for heart failure, 1.29 for CV death, 1.44 for death from CAD. However, BAC do not alarm radiologists; when reported, they are commonly mentioned as “present”, not impacting on CV decision-making. Of 18 published studies, 9 reported only presence/absence of BAC, 4 used a semi-quantitative scale, and 5 a continuous scale (with manual, automatic or semiautomatic segmentation). Various appearance, topological complexity, and vessels overlap make BAC quantification difficult to standardize. Nevertheless, machine learning approaches showed promising results in BAC quantification on mammograms. Conclusions: There is a strong rationale for mammography to become a dual test for breast cancer screening and CV disease prevention. However, robust and automated quantification methods are needed for a deeper insight on the association between BAC and CV disease, to stratifying CV risk and define personalized preventive actions. © 2019 Elsevier B.V.

Screening of specific quantitative peptides of beef by LC–MS/MS coupled with OPLS-DA

Item Type Journal Article**Author** C. Kang**Author** Y. Zhang**Author** M. Zhang**Author** J. Qi**Author** W. Zhao**Author** J. Gu**Author** W. Guo**Author** Y. Li

Abstract A rapid, simple, and efficient analysis methodology for screening specific quantitative peptides of beef was established based on liquid chromatography-tandem mass spectrometry (LC–MS/MS) coupled with orthogonal partial least squares-

discriminant analysis (OPLS-DA). The OPLS-DA model was built to select species-specific peptides that make a significant contribution to classification. Peptides with statistical significance were selected based on the variable importance in the projection (VIP) values and univariate P values. After the workflow of the statistical process, three specific quantitative peptides were identified by using homemade products with different beef contents. A quantification method for selected specific quantitative peptides was established by using LC–MS/MS. The quantitative results were applied to commercialized beef products. The developed method has high sensitivity, specificity, and repeatability. The results of this study proved that the integration of LC–MS/MS coupled with OPLS-DA is an efficient method for screening specific quantitative peptides and identification of the authenticity of meat products. © 2022

Seeking regularity from irregularity: unveiling the synthesis-nanomorphology relationships of heterogeneous nanomaterials using unsupervised machine learning

Item Type Journal Article

Author L. Yao

Author H. An

Author S. Zhou

Author A. Kim

Author E. Luijten

Author Q. Chen

Abstract Nanoscale morphology of functional materials determines their chemical and physical properties. However, despite increasing use of transmission electron microscopy (TEM) to directly image nanomorphology, it remains challenging to quantify the information embedded in TEM data sets, and to use nanomorphology to link synthesis and processing conditions to properties. We develop an automated, descriptor-free analysis workflow for TEM data that utilizes convolutional neural networks and unsupervised learning to quantify and classify nanomorphology, and thereby reveal synthesis-nanomorphology relationships in three different systems. While TEM records nanomorphology readily in two-dimensional (2D) images or three-dimensional (3D) tomograms, we advance the analysis of these images by identifying and applying a universal shape fingerprint function to characterize nanomorphology. After dimensionality reduction through principal component analysis, this function then serves as the input for morphology grouping through unsupervised learning. We demonstrate the wide applicability of our workflow to both 2D and 3D TEM data sets, and to both inorganic and organic nanomaterials, including tetrahedral gold nanoparticles mixed with irregularly shaped impurities, hybrid polymer-patched gold nanoprisms, and polyamide membranes with irregular and heterogeneous 3D crumple structures. In each of these systems, unsupervised nanomorphology grouping identifies both the diversity and the similarity of the nanomaterial across different synthesis conditions, revealing how synthetic parameters guide nanomorphology development. Our work opens possibilities for enhancing synthesis of nanomaterials through artificial intelligence and for understanding and controlling complex nanomorphology, both for 2D systems and in the far less explored case of 3D structures, such as those with embedded voids or hidden interfaces. © 2022 The Royal Society of Chemistry.

Abstract Introduction: Cardiovascular disease remains a leading cause of mortality worldwide, with atherosclerosis at its core. Accurate identification of vulnerable plaques is critical for preventing acute cardiovascular events. While optical coherence tomography (OCT) provides high-resolution imaging of plaque features, manual analysis is labor-intensive and operator-dependent. This study addresses the need for automated, accurate segmentation of atherosclerotic plaques in OCT pullbacks using advanced machine learning (ML) techniques. Methods: A comprehensive multi-center dataset of OCT pullbacks, encompassing 103 patients and annotated for key

plaque morphological features (lumen, fibrous cap, lipid core, and vasa vasorum), was used to tune, train and evaluate nine ML models, including U-Net, U-Net++, DeepLabV3, DeepLabV3+, FPN, LinkNet, PSPNet, PAN, and MA-Net. To address dataset imbalances and optimize performance for each plaque feature, we introduced a hybrid segmentation strategy: single-class models were deployed for highly prevalent features (e.g., lumen) and underrepresented classes (e.g., vasa vasorum), while a multi-class model targeted morphologically complex features with overlapping boundaries (e.g., fibrous cap and lipid core). Hyperparameter tuning was performed using Bayesian optimization, and segmentation accuracy was assessed with the Dice Similarity Coefficient (DSC) and other metrics. Results: The models achieved high segmentation accuracy for lumen (DSC: 0.987), fibrous cap (DSC: 0.736), and lipid core (DSC: 0.751), demonstrating the potential of leveraging ML techniques to enhance OCT's diagnostic capabilities. While lumen segmentation showed exceptional precision, the moderate accuracy for fibrous cap and lipid core highlights challenges with complex morphologies. Satisfactory results for vasa vasorum (DSC: 0.610) suggest areas for further refinement. By integrating these models into a weighted ensemble, taking into account class prevalence and model confidence, the combined system achieved a weighted DSC of 0.882 across all plaque features, a significant improvement over individual models. These findings confirm the hybrid strategy's ability to balance computational efficiency with accuracy through rigorous optimization, tailored model selection, and ensemble integration. Conclusion: This study presents a robust ML-driven framework for automated OCT segmentation that uses a hybrid approach and weighted ensemble learning to address class imbalance and feature complexity, significantly improving the accuracy and efficiency of atherosclerotic plaque analysis. The findings suggest potential clinical implications, including improved detection of high-risk plaques and enhanced decision-making in cardiovascular care. However, further prospective validation is required before clinical adoption. Future research should focus on expanding datasets, integrating multimodal imaging, and refining models for real-time clinical use, paving the way for transformative advancements in cardiovascular diagnostics. © 2025 The Authors

Segmentation of MS lesions using active contour model, adaptive mixtures method and MRF model

Item Type Conference Paper

Author A. Bijar

Author R. Khayati

Abstract This paper presents an approach for fully automatic segmentation of MS lesions in fluid attenuated inversion recovery (FLAIR) Magnetic Resonance (MR) images. The proposed method estimates a gaussian mixture model with three components as cerebrospinal fluid (CSF), normal tissue and MS lesions. To estimate this model, a region based Active Contour Model (ACM) is used to find the best initial values of model parameters. Then, Adaptive Mixture Method and Markov Random Field (MRF) model are utilized to obtain and upgrade the class conditional probability density function and the apriori probability of each class. After estimation of Model parameters and apriori probabilities, brain tissues are classified using Bayesian Classification. To evaluate the result of proposed method, the similarity criteria of different slices related to 20 MS patients are calculated and compared with other methods which include manual segmentation. Also, volume of segmented lesions are computed and compared with gold standard using correlation coefficient. The proposed method has better performance in comparison with previous works which are reported here. © 2011 University of Zagreb.

Author R. Khayati
Abstract The measurement or evaluation and clinical significance of human sperm morphology has always been and still is a controversial aspect of the semen analysis for the determination of a male's fertility potential. The evaluation of sperm size, shape and morphological smear characteristics should be assessed by carefully observing a stained sperm sample under a microscope. In order to avoid

subjectivity, numerous studies that incorporate image analysis techniques in the assessment of sperm morphology have been proposed. The primary step of all these methods is segmentation of sperm's parts. In this paper, we have proposed a new method for segmentation of sperm's Acrosome, Nucleus and Mid-piece. Sperm's Acrosome, Nucleus and Midpiece are segmented through a method based on a Bayesian classifier which utilizes the adaptive mixtures method (AMM) and Markov random field (MRF) model to obtain and upgrade the class conditional probability density function (CCPDF) and the apriori probability of each class. To compare the performance of the proposed approach with those of previous approaches including manual segmentation, the Accuracy, Sensitivity and Specificity were calculated. © 2012 IEEE.

Segmentation priors from local image properties: Without using bias field correction, location-based templates, or registration

Abstract We present a novel approach for generating information about a voxel's tissue class membership based on its signature—a collection of local image textures estimated over a range of neighborhood sizes. The approach produces a form of tissue class priors that can be used to initialize and regularize image segmentation. The signature-based approach is a departure from current location-based methods, which derive tissue class likelihoods based on a voxel's location in standard template space. To use location-based priors, one needs to register the volume in question to the template space, and estimate the image intensity bias field. Two optimizations, over more than a thousand parameters, are needed when high order nonlinear registration is employed. In contrast, the signature-based approach is independent of volume orientation, voxel position, and largely insensitive to bias fields. For these reasons, the approach does not require the use of population derived templates. The prior information is generated from variations in image texture statistics as a function of spatial scale, and an SVM approach is used to associate signatures with tissue types. With the signature-based approach, optimization is needed only during the training phase for the parameter estimation stages of the SVM hyperplanes, and associated PDFs; a training process separate from the segmentation step. We found that signature-based priors were superior to location-based ones aligned under favorable conditions, and that signature-based priors result in improved segmentation when replacing location-based ones in FAST (Zhang et al., 2001), a widely used segmentation program. SEISMIC RISK CLASSIFICATION OF NON-STRUCTURAL ELEMENTS

Item Type	Journal Article
Author	G.J. O'reilly
Author	G.M. Calvi
Abstract	Non-structural elements (NSEs) are those not forming part of a building's structural load-bearing system but are nevertheless subjected to dynamic forces and deformations during ground shaking. In terms of their role in building cost, NSEs make up approximately 82%, 87% and 92% of the total monetary investment for office, hotel and hospital buildings, respectively. Additionally, it has been shown that for a typical school building in Italy, NSEs comprise the majority (>60%) of the direct monetary losses induced at frequent levels of ground shaking. These two points alone highlight the critical nature of NSEs both from an initial investment and potential monetary loss perspective. The ability to quantify the seismic risk associated with structural and non-structural elements is a critical aspect of earthquake engineering. While methods to improve the understanding of structural response to earthquake shaking and how to quantify their risk have been studied, NSEs have recently emerged as a crucial aspect to address given their pertinence in overall building performance. This paper describes the formulation of a risk quantification methodology for NSEs whereby the mean annual frequency of exceeding an NSE's damage state is computed and rated as part of a risk classification scheme. The basis of the methodology is described followed by example implementations, where the details surrounding hazard, structural and non-structural response are quantified consistently, ensuring that uncertainties are also incorporated to be in line with modern performance-based earthquake engineering. This relates to both storey drift-sensitive and floor acceleration-sensitive non-structural elements that typically comprise most building fixtures and fittings in addition to the contents themselves. The result is a simple but effective methodology that may be used to directly quantify

and rank the risk associated with NSEs from a life safety, functionality and economic loss perspective. It may be implemented as part of a prioritisation scheme for building retrofit or also serve as a commercial instrument for NSE manufacturers, whereby their products can be marketed as having a certain rating class, to demonstrate superior seismic resilience with respect to others. © The 17th World Conference on Earthquake Engineering.

Selected machine learning of HOMO-LUMO gaps with improved data-efficiency

Item Type Journal Article

Author B. Mazouin

Author A.A. Schöpfer

Author O.A. von Lilienfeld

Abstract Despite their relevance for organic electronics, quantum machine learning (QML) models of molecular electronic properties, such as HOMO-LUMO-gaps, often struggle to achieve satisfying data-efficiency as measured by decreasing prediction errors for increasing training set sizes. We demonstrate that partitioning training sets into different chemical classes prior to training results in independently trained QML models with overall reduced training data needs. For organic molecules drawn from

previously published QM7 and QM9-data-sets we have identified and exploited three relevant classes corresponding to compounds containing either aromatic rings and carbonyl groups, or single unsaturated bonds, or saturated bonds. The selected QML models of band-gaps (considered at GW and hybrid DFT levels of theory) reach mean absolute prediction errors of ~ 0.1 eV for up to an order of magnitude fewer training molecules than for QML models trained on randomly selected molecules. Comparison to Δ -QML models of band-gaps indicates that selected QML exhibit superior data-efficiency. Our findings suggest that selected QML, e.g. based on simple classifications prior to training, could help to successfully tackle challenging quantum property screening tasks of large libraries with high fidelity and low computational burden. © 2022 RSC.

Selecting and Interpreting Multiclass Loss and Accuracy Assessment Metrics for Classifications with Class Imbalance: Guidance and Best Practices

Item Type Journal Article

Author S. Farhadpour

Author T.A. Warner

Author A.E. Maxwell

Abstract Evaluating classification accuracy is a key component of the training and validation stages of thematic map production, and the choice of metric has profound implications for both the success of the training process and the reliability of the final accuracy assessment. We explore key considerations in selecting and interpreting loss and assessment metrics in the context of data imbalance, which arises when the classes have unequal proportions within the dataset or landscape being mapped. The challenges involved in calculating single, integrated measures that summarize classification success, especially for datasets with considerable data imbalance, have led to much confusion in the literature. This confusion arises from a range of issues, including a lack of clarity over the redundancy of some accuracy measures, the importance of calculating final accuracy from population-based statistics, the effects of class imbalance on accuracy statistics, and the differing roles of accuracy measures when used for training and final evaluation. In order to characterize classification success at the class level, users typically generate averages from the class-based measures. These averages are sometimes generated at the macro-level, by taking averages of the individual-class statistics, or at the micro-level, by aggregating values within a confusion matrix, and then, calculating the statistic. We show that the micro-averaged producer's accuracy (recall), user's accuracy (precision), and F1-score, as well as weighted macro-averaged statistics where the class prevalences are used as weights, are all equivalent to each other and to the overall accuracy, and thus, are redundant and should be avoided. Our experiment, using a variety of loss metrics for training, suggests that the choice of loss metric is not as complex as it might appear to be, despite the range of choices available, which include cross-entropy (CE), weighted CE, and micro- and macro-Dice. The highest, or close to highest, accuracies in our experiments were obtained by using CE loss for models trained with balanced data, and for models trained with imbalanced data, the highest accuracies were obtained by using weighted CE loss. We recommend that, since weighted CE loss used with balanced training is equivalent to CE, weighted CE loss is a good all-round choice. Although Dice loss is commonly suggested as an alternative to CE loss when classes are imbalanced, micro-averaged Dice is similar to overall accuracy, and thus, is particularly poor for training with imbalanced data. Furthermore, although macro-Dice resulted in models with high accuracy when the training used balanced data, when the training used imbalanced data, the accuracies were lower than for weighted CE. In summary, the significance of this paper lies in its provision of readers with an overview of accuracy and loss metric terminology, insight regarding the redundancy of some measures, and guidance regarding best practices. © 2024 by the authors.

Selecting informative conformal prediction sets with false coverage rate control

Item Type Journal Article**Author** U. Gazin**Author** R. Heller**Author** A. Marandon**Author** E. Roquain

Abstract In supervised learning, including regression and classification, conformal methods provide prediction sets for the outcome/label with finite sample coverage for any machine learning predictor. We consider here the case where such prediction sets come after a selection process. The selection process requires that the selected prediction sets be ‘informative’ in a well-defined sense. We consider both the classification and regression settings where the analyst may consider as informative only the sample with prediction sets small enough, excluding null values, or obeying other appropriate ‘monotone’ constraints. We develop a unified framework for building such informative conformal prediction sets while controlling the false coverage rate (FCR) on the selected sample. While conformal prediction sets after selection have been the focus of much recent literature in the field, the new introduced procedures, called InfoSP and InfoSCOP, are to our knowledge the first ones providing FCR control for informative prediction sets. We show the usefulness of our resulting procedures on real and simulated data. © The Royal Statistical Society 2025. All rights reserved.

Selective Mixup Helps with Distribution Shifts, But Not (Only) because of Mixup

Abstract Context. Mixup is a highly successful technique to improve generalization by augmenting training data with combinations of random pairs. Selective mixup is a family of methods that apply mixup to specific pairs e.g. combining examples across classes or domains. Despite remarkable performance on benchmarks with distribution shifts, these methods are still poorly understood. Findings. We find that an overlooked aspect of selective mixup explains some of its success in a completely new light. The non-random selection of pairs affects the training distribution and improves generalization by means completely unrelated to the mixing. For example in binary classification, mixup across classes implicitly resamples the data to uniform class distribution — a classical solution to label

shift. We verify empirically that this resampling explains some of the improvements reported in prior work. Theoretically, the effect relies on a “regression toward the mean”, an accidental property we find in several datasets. Outcomes. We now better understand why selective mixup works. This lets us predict a yet-unknown failure mode and conditions where the method is detrimental. We also use the equivalence to resampling to design variants with better combinations of mixing and resampling. Copyright 2024 by the author(s)

Self-Assessment and Robust Anomaly Detection with Bayesian Deep Learning

Item Type Conference Paper

Author G. Carannante

Author D. Dera

Author O. Aminul

Author N.C. Bouaynaya

Author G. Rasool

Abstract Deep Learning (DL) models have achieved or even surpassed human-level accuracy in several areas, including computer vision and pattern recognition. The state-of-art performance of DL models has raised the interest in using them in real-world applications, such as disease diagnosis and clinical decision support

systems. However, the challenge remains the lack of trustworthiness and reliability of these DL models. The detection of incorrect decisions or flagging suspicious input samples is essential for the reliability of machine learning models. Uncertainty estimation in the output decision is a key component in establishing the trustworthiness and reliability of these models. In this work, we use Bayesian techniques to estimate the uncertainty in the model's output and use this uncertainty to detect distributional shifts linked to both input perturbations and labels shifts. We use the learned uncertainty information (i.e., the variance of the predictive distribution) in two different ways to detect anomalous input samples: 1) a static threshold based on average uncertainty of a model evaluated on the clean test data, and 2) a statistical threshold based on the significant increase in the average uncertainty of the model evaluated on corrupted (anomalous) samples. Our extensive experiments demonstrate that both approaches can detect anomalous samples. We observe that the proposed thresholding techniques can distinguish misclassified examples in the presence of noise, adversarial attacks, anomalies or distributional shifts. For example, when considering corrupted versions of MNIST and CIFAR-10 datasets, the rate of detecting misclassified samples is almost twice as compared to Monte-Carlo-based approaches. © 2022 International Society of Information Fusion.

Self-Organizing Map-Based Resilience Quantification and Resilient Control of Distribution Systems Under Extreme Events

Item Type Journal Article

Author K. Utkarsh

Author F. Ding

Abstract Due to climate change, extreme weather events are occurring more frequently and with increasing impact. This trend poses a significant challenge for distribution system operators (DSO) to ensure that there is uninterrupted power supply to critical loads in their networks. To embed resilience into DSO's decision-making, resilience needs to be first quantified and then integrated into the system-level optimization. Therefore, this paper first develops a novel self-organizing map (SOM) based method (called SomRes) to quantify the time-varying resilience index of a system that can leverage the powerful classification property of SOMs and removes some of the disadvantages of subjective weight assignment methods. Using SomRes, a resilient resource allocation and operational dispatch algorithm is further developed to enhance system resilience against extreme events by considering the SomRes resilience index directly as the feedback. The proposed resilience quantification approach is benchmarked with a state-of-the-art approach and the efficacy of the proposed resilient dispatch algorithm is demonstrated through several deterministic and statistical case studies on the IEEE 123-bus distribution system. Simulation studies show that the proposed SomRes quantification method is an appropriate indicator of system resilience, and the resilient resource allocation and dispatch strategy can significantly reduce critical load shedding under varying event propagation scenarios. © 2010-2012 IEEE.

Abstract Electroencephalography (EEG) is a non-invasive technique to record bioelectrical signals. Integrating supervised deep learning techniques with EEG signals has recently facilitated automatic analysis across diverse EEG-based tasks. However, the label issues of EEG signals have constrained the development of EEG-based deep models. Obtaining EEG annotations is difficult and requires domain experts to guide collection and labeling, and the variability of EEG signals among different subjects causes significant label shifts. To solve the above challenges, self-supervised learning (SSL) has been proposed to extract representations from unlabeled samples through well-designed pretext tasks. This article concentrates on integrating SSL frameworks with temporal EEG signals to achieve efficient representations and proposes a systematic survey of the SSL for EEG signals. In this article, (1) We introduce the concept and theory of self-supervised learning and typical SSL frameworks. (2) We provide a comprehensive survey of SSL for EEG analysis, including taxonomy, methodology, and technical details of the existing EEG-based SSL frameworks, and discuss the differences between these methods. (3) We investigate the adaptation of the SSL approach to various downstream tasks, including the task description and related benchmark datasets, and further explore its application in large-scale pre-trained foundation models for EEG signals. (4) Finally, we discuss the potential directions for future SSL-EEG research. © 2025 Copyright held by the owner/

Author M.-O. Coppens

Abstract The pore network architecture of porous heterogeneous catalyst supports has a significant effect on the kinetics of mass transfer occurring within them. Therefore, characterizing and understanding structure-transport relationships is essential to guide new designs of heterogeneous catalysts with higher activity and selectivity and superior resistance to deactivation. This study combines classical characterization via N₂ adsorption and desorption and mercury porosimetry with advanced scanning electron microscopy (SEM) imaging and processing approaches to quantify the spatial heterogeneity of γ -alumina (γ -Al₂O₃), a catalyst support of great industrial relevance. Based on this, a model is proposed for the spatial organization of γ -Al₂O₃, containing alumina inclusions of different porosities with respect to the alumina matrix. Using original, advanced SEM image analysis techniques, including deep learning semantic segmentation and porosity measurement under gray-level calibration, the inclusion volume fraction and interphase porosity difference were identified and quantified as the key parameters that served as input for effective tortuosity factor predictions using effective medium theory (EMT)-based models. For the studied aluminas, spatial porosity heterogeneity impact on the effective tortuosity factor was found to be negligible, yet it was proven to become significant for an inclusion content of at least 30% and an interphase porosity difference of over 20%. The proposed methodology based on machine-learning-supported image analysis, in conjunction with other analytical techniques, is a general platform that should have a broader impact on porous materials characterization. © 2024 The Authors. Semantic Density: Uncertainty Quantification for Large Language Models through Confidence Measurement in Semantic Space

Item Type Conference Paper**Author** X. Qiu**Author** R. Miikkulainen**Editor** Globerson A.**Editor** Mackey L.**Editor** Belgrave D.**Editor** Fan A.**Editor** Paquet U.**Editor** Tomczak J.**Editor** Zhang C.

Abstract With the widespread application of Large Language Models (LLMs) to various domains, concerns regarding the trustworthiness of LLMs in safety-critical scenarios have been raised, due to their unpredictable tendency to hallucinate and generate misinformation. Existing LLMs do not have an inherent functionality to provide the users with an uncertainty/confidence metric for each response it generates, making it difficult to evaluate trustworthiness. Although several studies aim to develop uncertainty quantification methods for LLMs, they have fundamental limitations, such as being restricted to classification tasks, requiring additional training and data, considering only lexical instead of semantic information, and being prompt-wise but not response-wise. A new framework is proposed in this paper to address these issues. Semantic density extracts uncertainty/confidence information for each response from a probability distribution perspective in semantic space. It has no restriction on task types and is "off-the-shelf" for new models and tasks. Experiments on seven state-of-the-art LLMs, including the latest Llama 3 and Mixtral-8x22B models, on four free-form question-answering benchmarks demonstrate the superior performance and robustness of semantic density compared to prior approaches. © 2024 Neural information processing systems foundation. Semantic-Constraint Matching for transformer-based weakly supervised object localization

Item Type Journal Article**Author** Y. Cao**Author** Y. Su**Author** W. Wang**Author** Y. Liu**Author** Q. Wu**Author** Q. Wu

Abstract Weakly supervised object localization (WSOL) strives to localize objects with only image-level supervision. WSOL often faces challenges such as incomplete localization due to classifier bias and over-localization in real scenes where objects and backgrounds are strongly associated or structurally similar. While the latest Transformer-based methods effectively enhance localization performance by leveraging long-range feature dependencies, they may inadvertently amplify divergent background activation and remain susceptible to classification bias. To this end, we proposed a novel Semantic-Constraint Matching (SeCM) plug-in module tailored for transformer-based approaches. In detail, a local patch shuffle strategy is first introduced to disentangle partial contextual linkages, thereby creating image pairs. Then a semantic matching module extracts co-object knowledge from the primal-shuffled image pairs, drives the network to identify the association of foreground with semantic label to suppress divergent activation. Moreover, to alleviate incomplete localization and prevent excessive suppression of activation, we propose leveraging multi-modal class-specific textual representations to guide object localization by complementing intra-class priori diverse knowledge. Extensive experimental results conducted on CUB-200-2011 and ILSVRC datasets show that our method can achieve the new state-of-the-art performance. © 2024 Elsevier Ltd

Semantic-Guided Multi-Vector Feature Representation for Few-Shot Image Classification

Item Type Conference Paper

Author X. Feng

Author L. Dong

Abstract Deep learning has achieved remarkable success across various fields, but its performance relies heavily on large-scale annotated data, limiting its application in real-world scenarios. Few-Shot Learning (FSL) provides an effective approach to address this data scarcity problem. Focusing on the key issues of feature extraction and feature representation in few-shot image classification tasks, this paper proposes a semantic-guided multi-vector feature representation method based on metric learning. In the feature extraction stage, an efficient Shuffle Attention (SA) mechanism is embedded into the ResNet-12 network to enhance the extraction of spatial and channel features from images. In terms of feature representation, semantic word vectors of categories are utilized to generate visual activation maps, which capture both the global and local features of the images. Furthermore, a base class prior knowledge transfer module is incorporated to transfer prior knowledge from base classes to novel classes, thereby enhancing the discriminability of novel class features. Experimental results on the

miniImageNet, CUB, and CIFAR-FS datasets demonstrate that the proposed model improves classification accuracy in both 5-way 1-shot and 5-way 5-shot tasks, with average increases of 1.25% and 1.11%, respectively. © 2026 IEEE.

Semi-supervised Sentiment Analysis of Portuguese Tweets with Random Walk in Feature Sample Networks

Item Type Conference Paper

Author P. Gengo

Author F.A.N. Verri

Editor Cerri R.

Editor Prati R.C.

Abstract Nowadays, a huge amount of data is generated daily around the world and many machine learning tasks require labeled data, which sometimes is not available. Manual labeling such amount of data may consume a lot of time and resources. One way to overcome this limitation is to learn from both labeled and unlabeled data, which is known as semi-supervised learning. In this paper, we use a positive-unlabeled (PU) learning technique called Random Walk in Feature-Sample Networks (RWFSN) to perform semi-supervised sentiment analysis, which is an important machine learning that can be achieved by classifying the polarity of texts, in Brazilian Portuguese tweets. Although RWFSN reaches excellent performance in many PU learning problems, it has two major limitations when applied in our problem: it assumes that samples are long texts (many features) and that the class prior probabilities are known. We leverage the technique by augmenting the data representation in the feature space and by adding a validation set to better estimate the class priors. As a result, we identified unlabeled samples of the positive class with precision around at 70% in higher labeled ratio, but with high standard deviation, showing the impact of data variance in results. Moreover, given the properties of the RWFSN method, we provide interpretability of the results by pointing out the most relevant features of the task. © 2020, Springer Nature Switzerland AG.

Semi-supervised Bayesian classification by vector features with continuous and discrete components

Item Type Conference Paper

Author V.O. Vasilyev

Author A.V. Dobrovidov

Abstract A solution for the traditional Bayesian classification problem in non-traditional conditions is proposed, when the distributions and a priori probabilities of classes are unknown, but a trained sample from the zero class (labeled positive) and mixed sample (unlabeled) are available. Mixed sample will be employed in the learning to restore mixed distribution and as a test sample for constructed classifier. The case with vector features containing continuous and discrete components is considered. To restore unknown distributions nonparametric kernel techniques with data-driven bandwidth are used. A new algorithm for estimating the prior probability of zero class is given using positive labeled and unlabeled samples. This allows to find a good approximation of optimal threshold for the modified Bayesian classification algorithm. Numerical verification confirms the effectiveness of the proposed classification technique even in cases of strong overlapping of class distributions. © 2017 IEEE.

Semi-supervised clinical text classification with Laplacian SVMs: An application to cancer case management

Item Type Journal Article**Author** V. Garla**Author** C. Taylor**Author** C. Brandt

Abstract Objective: To compare linear and Laplacian SVMs on a clinical text classification task; to evaluate the effect of unlabeled training data on Laplacian SVM performance. Background: The development of machine-learning based clinical text classifiers requires the creation of labeled training data, obtained via manual review by clinicians. Due to the effort and expense involved in labeling data, training data sets in the clinical domain are of limited size. In contrast, electronic medical record (EMR) systems contain hundreds of thousands of unlabeled notes that are not used by supervised machine learning approaches. Semi-supervised learning algorithms use both labeled and unlabeled data to train classifiers, and can outperform their supervised counterparts. Methods: We trained support vector machines (SVMs) and Laplacian SVMs on a training reference standard of 820 abdominal CT, MRI, and ultrasound reports labeled for the presence of potentially malignant liver lesions that require follow up (positive class prevalence 77%). The Laplacian SVM used 19,845 randomly sampled unlabeled notes in addition to the training reference standard. We evaluated SVMs and Laplacian SVMs on a test set of 520 labeled reports. Results: The Laplacian SVM trained on labeled and unlabeled radiology reports significantly outperformed supervised SVMs (Macro-F1 0.773 vs. 0.741, Sensitivity 0.943 vs. 0.911, Positive Predictive value 0.877 vs. 0.883). Performance improved with the number of labeled and unlabeled notes used to train the Laplacian SVM (pearson's $\rho=0.529$ for correlation between number of unlabeled notes and macro-F1 score). These results suggest that practical semi-supervised methods such as the Laplacian SVM can leverage the large, unlabeled corpora that reside within EMRs to improve clinical text classification. © 2013 Elsevier Inc.

Semi-supervised deep learning for high-dimensional uncertainty quantification

Item Type Conference Paper**Author** Z. Wang**Author** M. Li

Abstract Conventional uncertainty quantification methods usually lacks the capability of dealing with high-dimensional problems due to the curse of dimensionality. This paper presents a semisupervised learning framework for dimension reduction and reliability analysis. An autoencoder is first adopted for mapping the high-dimensional space into a low-dimensional latent space, which contains a distinguishable failure surface. Then a deep feedforward neural network (DFN) is utilized to learn the mapping relationship and reconstruct the latent space, while the Gaussian process (GP) modeling technique is used to build the surrogate model of the transformed limit state function. During the training process of the

DFN, the discrepancy between the actual and reconstructed latent space is minimized through semisupervised learning for ensuring the accuracy. Both labeled and unlabeled samples are utilized for defining the loss function of the DFN. Evolutionary algorithm is adopted to train the DFN, then the Monte Carlo simulation method is used for uncertainty quantification and reliability analysis based on the proposed framework. The effectiveness is demonstrated through a mathematical example. Copyright © 2020 ASME.

Semi-supervised intracranial aneurysm segmentation via reliable weight selection

Item Type Journal Article

Author W. Cao

Author X. Chen

Author J. Lv

Author L. Shao

Author W. Si

Abstract Early detection of intracranial aneurysms (IA) is crucial for risk reduction and treatment planning. Computed tomography angiography (CTA) has been widely applied in IA screening due to its rapid, cost-effective, and high-resolution capabilities. However, manual segmentation of IA from CTA images is labor-intensive and time-consuming, highlighting the urgent need for automated segmentation methods to improve diagnostic efficiency. This paper presents a reliable weight selection mean teacher framework for IA segmentation, leveraging semi-supervised learning to enhance network performance with limited labeled data. The framework consists of a student network and two teacher networks, while the teacher networks generate adversarial noise to guide the student network in learning. A novel reliable sample weight selection module employs ensemble learning to quantify prediction weights adaptively to minimize errors from individual models. Additionally, we integrate xLSTM module into the segmentation network to capture the contextual features between frames in the input data, while adversarial noise is introduced to bolster model robustness. Experiments show that our method improves Dice scores by at least 4.8% compared to the fully-supervised segmentation model baseline and at least 1.1% compared to other state-of-the-art semi-supervised methods under 20% labeled data. Semi-supervised learning of class balance under class-prior change by distribution matching

Item Type Conference Paper

Author M.C. Du Plessis

Author M. Sugiyama

Abstract In real-world classification problems, the class balance in the training dataset does not necessarily reflect that of the test dataset, which can cause significant estimation bias. If the class ratio of the test dataset is known, instance re-weighting or resampling allows systematical bias correction. However, learning the class ratio of the test dataset is challenging when no labeled data is available from the test domain. In this paper, we propose to estimate the class ratio in the test dataset by matching probability distributions of training and test input data. We demonstrate the utility of the proposed approach through experiments. Copyright 2012 by the author(s)/owner(s).

Semi-Supervised Learning Using Gaussian Fields and Harmonic Functions

Item Type Conference Paper**Author** X. Zhu**Author** Z. Ghahramani**Author** J. Lafferty

Abstract An approach to semi-supervised learning is proposed that is based on a Gaussian random field model. Labeled and unlabeled data are represented as vertices in a weighted graph, with edge weights encoding the similarity between instances. The learning problem is then formulated in terms of a Gaussian random field on this graph, where the mean of the field is characterized in terms of harmonic functions, and is efficiently obtained using matrix methods or belief propagation. The resulting learning algorithms have intimate connections with random walks, electric networks, and spectral graph theory. We discuss methods to incorporate class priors and the predictions of classifiers obtained by supervised learning. We also propose a method of parameter learning by entropy minimization, and show the algorithm's ability to perform feature selection. Promising experimental results are presented for synthetic data, digit classification, and text classification tasks.

Semi-supervised learning with local and global consistency

Item Type Journal Article

Author J. Gui

Author R. Hu

Author Z. Zhao

Author W. Jia

Abstract In a lot of practical machine learning applications, such as web page classification, protein shape classification, unlabelled instances are easy to obtain, but labelled instances are rather too expensive to get. Thus, recently, semi-supervised learning (SSL) methods including graph-based algorithms have attracted many interests from researchers. However, most of these algorithms used the Gaussian function to calculate weights of the edge of the graph. In this paper, we proposed a novel weight for graph-based semi-supervised algorithms. In this new algorithm, the label information is added from problem into SSL algorithm, and the geodesic distance is utilized instead of Euclidean distance to calculate the distance between two instances. Furthermore, class prior knowledge is also added from problem into the target function. In this paper, we focus on learning with local and global consistency. We found that the effect of class prior knowledge maybe different between under low-label rate and high-label rate. Experiments on two University of California Irvine (UCI) data sets and United States Postal Service handwritten digit recognition show that our proposed algorithm is really effective. © 2013, Taylor & Francis.

Semi-supervised learning with local and global consistency by geodesic distance and sparse representation

Item Type Conference Paper

Author J. Gui

Author Z. Zhao

Author R. Hu

Author W. Jia

Abstract In many practical data mining applications, such as web categorization, key gene selection, etc., generally, unlabeled training examples are readily available, but labeled ones are fairly expensive to obtain. Therefore, in recent years, semi-supervised learning algorithms such as graph-based methods have attracted much attention. However, most of these traditional methods adopted a Gaussian function to calculate the edge weights of the graph. In this paper, a novel weight for semi-supervised graph-based methods is proposed. The new method adds the label information from problem into the target function, and adopts the geodesic distance rather than Euclidean distance as the measure of the difference between two data points when conducting the calculation. In addition, we also add class prior knowledge from problem into semi-supervised learning algorithm. Here we address the problem of learning with local and global consistency (LGC). It was found that the effect of class prior knowledge was probably different between under high label rate and low label rate. Furthermore, we integrate sparse representation (SR) in LGC algorithm. Experiments on a UCI data set show that our proposed method outperforms the original algorithms. © Springer-Verlag 2013.

Semi-supervised sufficient dimension reduction under class-prior change

Item Type Conference Paper
Author H. Kawakubo
Author M. Sugiyama
Abstract Sufficient dimension reduction (SDR) is a popular framework for supervised dimension reduction, aiming at reducing the dimensionality of input data while information on output data is maximally maintained. On the other hand, in many recent supervised classification learning tasks, it is conceivable that the balance of samples in each class varies between the training and testing phases. Such a phenomenon, referred to as class-prior change, causes existing SDR methods to perform undesirably particularly when the training data is highly imbalanced. In this paper, we extend the state-of-the-art SDR method called leastsquares gradients for dimension reduction (LSGDR) to be able to cope with such class-prior change under the semi-supervised learning setup where unlabeled test data are available in addition to labeled training data. Through experiments, we demonstrate the usefulness of our proposed method. © 2016 IEEE.

Abstract PURPOSE. To describe and evaluate a semiquantitative optic nerve grading scheme for assessing axonal loss in endothelin (ET)-1-induced chronic optic neuropathy. METHODS. Optic nerve cross-sections from both eyes of 39 Brown Norway rats unilaterally treated with various concentrations of ET-1 or physiological saline solution via a surgically implanted osmotic minipump were processed for light and transmission electron microscopy (TEM). The optic nerve damage grade, between 0 (no damage) and 10 (total damage), was based on the number of zones of approximately equal damage and the mean percentage of damage within each zone. Grading was performed under light microscopy by three observers and compared with axonal survival determined with TEM using two quantification methods: the sampling method, in which ~10% of the section was counted, and the full-count

method, in which the whole section was counted ($n = 12$). Axonal survival was expressed as a ratio of axon counts in the experimental to control eye. Before these comparisons, the interand intraobserver agreement rates were determined in another group of 85 and 12 ET-1-treated animals, respectively. RESULTS. The interobserver κ was 0.66 (95% confidence interval [CI]: 0.58-0.74) for all eyes and 0.55 (95% CI: 0.43- 0.67) for the experimental eyes only. The intraobserver κ was 0.80, 0.81, and 0.80 for all 24 eyes and 0.60, 0.64, and 0.71 for experimental eyes only. The correlation between damage grade in the experimental eye and axonal survival using the TEM sampling method (Spearman's $\rho = -0.677$ for all animals and -0.827 for the subset of animals with full counts only) was lower than that with the full-count method (Spearman's $\rho = -0.926$). When axonal survival was less than 0.7, the sampling method always underestimated the extent of damage. CONCLUSIONS. The grading scheme had good inter- and intraobserver agreement, and high correlation with the TEM methods. It is a practical and time-saving method, requiring less than 1 minute per nerve and is an alternative to sampling methods that can yield significant errors. Abstract The Semmeldetector, is a machine learning application that utilizes object detection models to detect, classify and count baked goods in images. Our application allows commercial bakers to track unsold baked goods, which allows them to op-timize production and increase resource efficiency. We compiled a dataset comprising 1151 images that distinguishes between 18 different types of baked goods to train our detection models. To facilitate model training, we used a Copy-Paste augmentation pipeline to expand our dataset. We trained the state-of-the-art object detection model YOLOv8 on our detection task. We tested the impact of different training data, model scale, and online image augmentation pipelines on model performance. Our overall best performing model, achieved an AP_{0.5} of 89.1 % on our test set. Based on our results, we conclude that machine learning can be a valuable tool even for unforeseen industries like bakeries, even with very limited datasets. © 2023 IEEE.

Sensor placement optimization for shm systems under uncertainty

Item Type Conference Paper

Author R.F. Guratzsch

Author S. Mahadevan

Author C.L. Pettit

Author M.M. Derriso

Abstract Structural Health Monitoring (SHM) systems that report in real-time a flight vehicle's condition are central to meeting the goals of increasing flight vehicle safety and reliability, while reducing operating and maintenance costs. The structural response of flight vehicles is inherently random, requiring deterministic finite element analyses to be augmented with uncertainty quantification methods to compute the response statistics and structural damage probability. To detect damage with maximum probability, sensors must be placed optimally. This requires combining a probabilistic finite element method (FEM) with damage detection algorithms and optimization techniques. This study develops a methodology to integrate the above disciplines into a sensor placement optimization (SPO) methodology for SHM systems under uncertainty. To achieve this, the structural component under consideration is analyzed via FEM and uncertainty of model input quantities is included in the analysis via random processes and fields. In the next two steps probabilistic FEM analyses are performed to determine the model output variability and using these results, damage detection procedures such as feature extraction and state classification are applied to assess the current structural state of the component. Repeating these two steps using both healthy and damaged structural models helps quantify the reliability of a given sensor layout. Finally, SPO is achieved to maximize the reliability of damage detection. The sensor layout design of a thermal protection system component is used as a numerical example. Sensory-Driven Design Method for Personalizing Ride Comfort Tailored to Individual Vibration Perception

Item Type Conference Paper
Author H. Kikuchi
Author K. Inaba
Abstract This study aims to develop a design method that tailors the ride comfort and design variables of vehicle components according to individual differences in vibration perception. In conventional development, variations in vibration perception have been recognized; however, quantification methods remain undeveloped, preventing designs from being adapted to individual driver perceptions. The two unresolved problems include the uniformization of vibration perception in sensory performance modeling, which predicts sensory scores from vehicle vibrations, and design approaches that focus on minimizing vehicle vibrations without considering vibration perception. First, the authors' previous study quantified the existence of individual differences in vibration perception

through sensory scores obtained from ride simulator experiments involving 24 non-expert drivers using vibrations derived from a uniform vibration perception. Hierarchical clustering identified four perception groups; however, the reduced sample sizes resulting from the classification necessitated an uncertainty evaluation in the sensory performance modeling. This study formulated personalized sensory performance models for each group using an ensemble learning method with bootstrap resampling data to enable an uncertainty assessment. These models demonstrated sufficient prediction accuracy for sensory scores through cross-validation. Second, these models were integrated into a sensory-driven design method previously proposed by the authors to maximize sensory scores. This integrated method was validated by designing a unique electronically controlled damper system that yielded personalized solutions for ride comfort and design variables tailored to the vibration perception of each group. The practicality of the method lies in the personalization of vehicle performances with the potential for enhanced tailoring in future Software Defined Vehicles. © 2025 SAE International. Sentiment Quantification of User-Generated Content

Item Type Journal Article

Author F. Sebastiani

Abstract Prevalence of c in set S : Percentage of items in S that belong to class c and also known as the “relative frequency” of c or the “prior probability” (or simply “prior”) of c Quantification: Estimation of the prevalence of each class $c \in C$ in a set S of unlabeled items (or estimation of the distribution of S across the classes in C), synonym of “supervised prevalence estimation” and “class prior estimation,” and also previously referred to as “counting.” Sentiment classification: A classification task whereby items (e.g., tweets, product reviews, comments, answers to open-ended questions) are classified based on the sentiment they convey (or opinion they express) about a certain entity or topic. It may take the form of binary classification (when the available classes are $C = \{\text{POSITIVE}, \text{NEGATIVE}, \dots\}$). © Springer Science+Business Media New York 2014.

Abstract We introduce a novel approach for detecting distribution shifts that negatively impact the performance of machine learning models in continuous production environments, which requires no access to ground truth data labels. It builds upon the work of Podkopaev and Ramdas [2022], who address scenarios where labels are available for tracking model errors over time. Our solution extends this framework to work in the absence of labels, by employing a proxy for the true error. This proxy is derived using the predictions of a trained error estimator. Experiments show that our method has high power and false alarm control under various distribution shifts, including covariate and label shifts and natural shifts over geography and time. © 2024 Neural information processing systems foundation. Sequential label shift detection in classification data: An application to dengue fever

Item Type Journal Article

Author C. Evans

Author M.G. Sell

Abstract Classifiers have been developed to help diagnose dengue fever in patients presenting with febrile symptoms. However, classifier predictions often rely on the assumption that new observations come from the same distribution as training data. If the population prevalence of dengue changes, as would happen with a dengue outbreak, it is important to raise an alarm as soon as possible, so that appropriate public health measures can be taken and also so that the classifier can be re-calibrated. In this paper, we consider the problem of detecting such a change in distribution in sequentially-observed, unlabeled classification data. We focus on label shift changes to the distribution, where the class priors shift but the class conditional distributions remain unchanged. We reduce this problem to the problem of detecting a change in the one-dimensional classifier scores, leading to simple nonparametric sequential changepoint detection procedures. Our procedures leverage classifier training data to estimate the detection statistic, and converge to their parametric counterparts in the size of the training data. In simulated outbreaks with real dengue data, we show that our method outperforms other detection procedures in this label shift setting. © 2024 Evans, G'Sell. Sequential surrogate modeling for inverse design with conformal inference-based uncertainty quantification

Item Type Journal Article

Author H. Wu

Author Y. Xu

Abstract Inverse design poses challenges due to its nonlinear, high-dimensional, and often ill-posed nature. Machine learning has emerged as a promising alternative, offering cost-effective alternatives to computationally expensive models but can yield inconsistent or non-physical results without proper uncertainty quantification. This research introduces a novel framework that integrates uncertainty quantification into inverse design using sequential machine learning-based surrogate modeling. The framework operates through two key processes: a trainee model that identifies candidate design inputs expected to produce the desired outputs, and an assessor that applies conformal inference, guided by a user-defined confidence level, to evaluate and filter these candidates. By eliminating unreliable predictions, the framework delivers robust and accurate design solutions. Notably, the proposed approach is model-agnostic and does not rely on predefined prior distributions or model-specific likelihoods, distinguishing it from Bayesian-based uncertainty quantification methods. We validate the approach through one mathematical example and three engineering case studies. Results demonstrate that our method provides more robust and accurate solutions compared to conventional single-model approaches for inverse design. © 2025 Elsevier Ltd.

Abstract Molecular and serological data suggest that noroviruses (NoVs) might be transmitted between humans and domestic carnivores. In this study we screened an age-stratified collection of canine sera (n = 516) by using an ELISA assay based on virus-like particles (VLPs) of human NoVs GII.4 and GIV.1 and carnivore NoVs GIV.2 and GVI.2. Antibodies against GII.4 and GIV.1 human NoVs and GIV.2 and GVI.2 NoVs from carnivores were identified in dog sera (13.0%, 67/516) suggesting their exposure to homologous and heterologous NoVs. Analysis of the trends of age-class prevalence showed a gradual increase in the positive rate from 9.0% and 7.0%, in young dogs <1 year of age to 15.0% in dogs older than 12 years, for GII.4 and GVI.2 NoVs, respectively. A significant difference in the IgG distribution by age classes was observed for GIV.1 NoVs, with the highest rate of antibodies (7.0%) in the age

group <1 year and the lowest (1.0%) in the age-classes 7–9 ($P = 0.049$). High correlation between the reactivity to GII.4 and GVI.2 NoVs was observed, likely due to conserved epitopes in the capsid structure. © 2017 Elsevier B.V.

Shaping the Anthropocene: Understanding and Evaluating Human Impact on the Global Ecosystem

Item Type Journal Article

Author Y. Ding

Abstract In the Anthropocene epoch, human activities have extensively altered the global ecological system, leading to substantial shifts in species distribution and survival patterns due to industrialization and global warming. Quantifying these environmental impacts is essential; for example, the 2023 Global Footprint Network estimates humanity's ecological footprint to be 1.71 Earths, underscoring the urgent need for sustainable solutions. This study aims to identify and summarize primary quantification methods for assessing human impacts on the environment. Using the Web of Science database, this paper analyzes 1000 relevant papers to identify four primary methodologies: the ecological footprint, Human Appropriation of Net Primary Production (HANPP), the Planetary Boundary framework, and the Living Planet Index (LPI). This paper provides a detailed evaluation of each approach, assessing their strengths and limitations in measuring the effects of human activities on the global ecosystem. Additionally, this study explores the potential of machine learning models to enhance future predictions. By analyzing and comparing these methods, this paper offers insights that are critical for informing policies and practices aimed at reducing human-induced environmental degradation. © 2025 Wiley Periodicals LLC.

Shapley Value Approximation Based on k-Additive Games

Item Type Conference Paper

Author G.D. Pelegrina

Author P. Kolpaczki
Author E. Hüllermeier
Editor Koenig S.
Editor Jenkins C.
Editor Taylor M.E.

Abstract The Shapley value is the prevalent solution for fair division problems in which a payout is to be divided among multiple agents. By adopting a game-theoretic view, the idea of fair division and the Shapley value can also be used in machine learning to quantify the individual contribution of features or data points to the performance of a predictive model. Despite its popularity and axiomatic justification, the Shapley value suffers from a computational complexity that scales exponentially with the number of entities involved, and hence requires approximation methods for its reliable estimation. We propose SVakADD, a novel approximation method that fits a k-additive surrogate game. By taking advantage of k-additivity, we are able to elicit the exact Shapley values of the surrogate game and then use these values as estimates for the original fair division problem. The efficacy of our method is evaluated empirically and compared to competing methods. © 2026, Association for the Advancement of Artificial Intelligence (www.aaai.org). All rights reserved.

Shapley-based fault variable identification in MSPC

Item Type Journal Article

Author J. Lim

Author J. Kim

Author S. Lee

Author S. Lee

Abstract In multivariate statistical process control, Hotelling's (Formula presented.) control chart (HT chart) is a powerful tool for detecting shifts in a process's overall mean. However, when a process falls out of control, the HT chart only signals an issue without identifying the specific variables responsible for the deviation. To address this limitation, traditional approaches decompose the overall (Formula presented.) statistic into (Formula presented.) statistics of individual variables or higher-order interaction terms. While informative, this approach becomes computationally challenging and less effective as the number of variables increases. In this study, we propose a new procedure based on the Shapley value, widely applied in machine learning to quantify variable importance in predictions. In this approach, we consider the (Formula presented.) statistic as a value function for each subset of variables and employ Shapley sampling and KernelSHAP to estimate Shapley values in high dimensional data. Most importantly, we develop a procedure to identify variable causing the out of control signal using Shapley values, demonstrating that Shapley values serve as an e-value. We numerically compare the performance of this new Shapley-based procedure with two existing procedures: the Mason-Tracy-Young and the adaptive step-down procedures. Finally, we apply these procedures to detect changes in the monthly temperature of Seoul after the year 2000. © 2026 Taylor & Francis Group, LLC.

Shift-Aware Stacking Ensemble with Conformal Prediction for Brain Stroke Detection

Item Type Conference Paper

Author S. Batchala

Author T. Kamble

Author V. Katkam

Author B. Mallikarjuna

Abstract Machine learning models for clinical risk prediction often lose accuracy when used in new environments because of domain shift, where the training (source) and testing (target) data differ. This paper introduces a shift-aware framework for brain stroke detection that adapts a model trained on a large cardiovascular disease dataset to a stroke-specific population. The proposed multistage approach handles both covariate and label shifts through careful data preprocessing, feature alignment, and domain shift measurement using a domain classifier. The study reduces covariate shift through importance weighting, and trains stacking ensemble of Gradient Boosting models such as LightGBM, XGBoost, CatBoost, and Random Forest, on the weighted data in order to increase predictive accuracy. The ensemble's results are then measured with Isotonic Regression and filtered using conformal prediction to provide reliable, distribution free uncertainty estimates. On the target stroke dataset, the method achieves a ROC AUC of 0.972 and a PR AUC of 0.976, introducing effective knowledge transfer over domains. By combining calibration and conformal prediction, this framework gives trustworthy confidence measures, making it suitable for clinical use where reliability is essential. © 2025 IEEE.

Abstract There has been significant research done on developing methods for improving robustness to distributional shift and uncertainty estimation. In contrast, only limited work has examined developing standard datasets and benchmarks for assessing these approaches. Additionally, most work on uncertainty estimation and robustness has developed new techniques based on small-scale regression or image classification tasks. However, many tasks of practical interest have different modalities, such as tabular data, audio, text, or sensor data, which offer significant challenges involving regression and discrete or continuous structured prediction. Thus, given the current state of the field, a standardized large-scale dataset of tasks across a range of modalities affected by distributional shifts is necessary. This will enable researchers to meaningfully evaluate the plethora of recently developed uncertainty quantification methods, as well as assessment criteria and state-of-the-art baselines. In this work, we propose the Shifts Dataset for evaluation of uncertainty estimates and robustness to distributional shift. The dataset, which has been collected from industrial sources and services, is composed of three tasks, with each corresponding to a particular data modality: tabular weather prediction, machine translation, and self-driving car (SDC) vehicle motion prediction. All of these data modalities and tasks are affected by real, “in-the-wild” distributional shifts and pose interesting challenges with respect to uncertainty estimation. In this work we provide a description of the dataset and baseline results for all tasks. © 2021 Neural information processing systems foundation. All rights reserved.

Sicca syndrome in the same family – The importance of anti-Ro60, anti-Ro52 and anti-La antibody profiling in Sjögren's syndrome

Item Type Journal Article

Author A. Koszarny

Author M. Majdan

Abstract Sicca syndrome, which is typical for Sjögren's syndrome (SS), both primary (pSS) and secondary (sSS), is relatively often comorbid with other autoimmune diseases. The current classification criteria for SS published in 2016 include only anti-SSA (anti-Ro) autoantibody, while the latest literature proposes that anti-Ro60/anti-Ro52 autoantibody profiles should be used instead, as these two types of antibodies correlate with specific clinical symptoms and laboratory test findings. The paper presents the case of a 41-year-old woman suffering from pSS and her three daughters, who were under observation for rheumatic disorders due to sicca symptoms, especially pSS, as well as a discussion on separate determination of anti-Ro60 and anti-Ro52 autoantibodies based on current literature in the PubMed database. When testing with antinuclear antibodies, the Ro60+Ro52+La+ autoantibody profile most closely matches for pSS. Further research is needed to find marker antibodies for SS and quantification methods. © 2021 Termedia Publishing House Ltd.. All rights reserved.

Abstract The intelligent cyber-physical system (CPS) has been applied in various fields, covering multiple critical infras-tructures and human daily life support areas. CPS Security is a major concern and of critical importance, especially the security of the intelligent control component. Side-channel analysis (SCA) is the common threat exploiting the weaknesses in system operation to extract information of the intelligent CPS. However, existing literature lacks the systematic theo-retical analysis of the side-channel attacks on the intelligent CPS, without the ability to quantify and measure the leaked information. To address these issues, we propose the SCA-based model extraction attack on intelligent CPS. First, we design an efficient and novel SCA-based model extraction framework, including the threat model, hierarchical attack process, and the multiple micro-space parallel search enabled weight extraction algorithm. Secondly, an information theory-empowered analy-sis model for side-channel attacks on intelligent CPS is built. We propose a mutual information-based quantification method and derive the capacity of side-channel attacks on intelligent CPS, formulating the amount of information leakage through side channels. Thirdly, we develop the theoretical bounds of the leaked information over multiple attack queries based on the data processing inequality and properties of entropy. These convergence bounds provide theoretical means to estimate the amount of information leaked. Finally, experimental evaluation, including real-world experiments, demonstrates the effective-ness of the proposed SCA-based model extraction algorithm and the information theory-based analysis method in intelligent CPS. © 2021 IEEE.

Simplified and representative bacterial community of maize roots

Item Type Journal Article

Author B. Niu

Author J.N. Paulson

Author X. Zheng

Author R. Kolter

Abstract Plant-associated microbes are important for the growth and health of their hosts. As a result of numerous prior studies, we know that host genotypes and abiotic factors influence the composition of plant microbiomes. However, the high complexity of these communities challenges detailed studies to define experimentally the mechanisms underlying the dynamics of community assembly and the beneficial effects of such microbiomes on plant hosts. In this work, from the distinctive microbiota assembled by maize roots, through host-mediated selection, we obtained a greatly simplified synthetic bacterial community consisting of seven strains (*Enterobacter cloacae*, *Stenotrophomonas maltophilia*, *Ochrobactrum pituitosum*, *Herbaspirillum frisingense*, *Pseudomonas putida*, *Curtobacterium pusillum*, and *Chryseobacterium indologenes*) representing three of the four most dominant phyla found in maize roots. By using a selective culture-dependent method to track the abundance of each strain, we investigated the role that each plays in community assembly on roots of axenic maize seedlings. Only the removal of *E. cloacae* led to the complete loss of the community, and *C. pusillum* took over. This result suggests that *E. cloacae* plays the role of keystone species in this model ecosystem. In planta and in vitro, this model community inhibited the phytopathogenic fungus *Fusarium verticillioides*, indicating a clear benefit to the host. Thus, combined with the selective culture-dependent quantification method, our synthetic seven-species community representing the root microbiome has the potential to serve as a useful system to explore how bacterial interspecies interactions affect root microbiome assembly and to dissect the beneficial effects of the root microbiota on hosts under laboratory conditions in the future.

Editor Berkenkamp F.

Abstract Recent advancements in semi-supervised learning have focused on a more realistic yet challenging task: addressing imbalances in labeled data while the class distribution of unlabeled data remains both unknown and potentially mismatched. Current approaches in this sphere often presuppose rigid assumptions regarding the class distribution of unlabeled data, thereby limiting the adaptability of models to only certain distribution ranges. In this study, we propose a novel approach, introducing a highly adaptable framework, designated as SimPro, which does not rely on any predefined assumptions about the distribution of unlabeled data. Our framework, grounded in a probabilistic model, innovatively refines the expectation-maximization (EM) algorithm by explicitly decoupling the modeling of conditional and marginal class distributions. This separation facilitates a closed-form solution for class distribution estimation during the maximization phase, leading to the formulation of a Bayes classifier.

The Bayes classifier, in turn, enhances the quality of pseudo-labels in the expectation phase. Remarkably, the SimPro framework not only comes with theoretical guarantees but also is straightforward to implement. Moreover, we introduce two novel class distributions broadening the scope of the evaluation. Our method showcases consistent state-of-the-art performance across diverse benchmarks and data distribution scenarios. Our code is available at <https://github.com/LeapLabTHU/SimPro>. Abstract Background: Adipose tissue is a dynamic endocrine organ, a highly active metabolic tissue, and an important source of cytokines. Inflammatory factors play an important role in visceral obesity associated with insulin resistance (IR), metabolic syndrome (MS), hypertension, non-alcoholic fatty liver disease (NAFLD), diabetes mellitus type 2 (DM2), endothelial dysfunction (ED) and atherosclerosis. Objectives: To examine correlation of siMS score, as a quantification method for metabolic syndrome (MS), with insulin resistance, glucoregulation parameters, as with other co-founding factors of MS, inflammation and thrombosis factors, microalbuminuria, uric acid, fatty liver index (FLI) and homocysteine. Methods: The study included 451 obese individuals with pre-metabolic syndrome (pre-MS) and MS (age 16–75, body mass index (BMI) > 25kg/m²) classified into two groups: I-age 10–30 (167 patients); II-age 31–75 (284 patients). International Diabetes Federation (IDF) classification was applied for diagnosing metabolic syndrome. Patients with less than three criteria indicated below were considered pre-metabolic syndrome. siMS risk score was used. Results: siMS score increased with age: I- 3.03 ± 0.87 , II- 3.27 ± 0.90 . siMS score correlated with associated factors of MS: hyperinsulinemia and IR, ALT, gama-GT, FLI, uric acid in both groups and CRP ($p < 0.01$) in group I. Correlations in II group: siMS score with PAI-1 ($p = 0.01$), microalbuminuria ($p = 0.006$), homocysteine ($p = 0.076$). Conclusion: Correlation of siMS score with HOMA-IR confirmed that hyperinsulinism and insulin resistance are in the basis of MS. Correlation of siMS score with parameters of NAFLD, CRP, PAI-1, uric acid, microalbuminuria and homocysteine indicates that they are significant co-founding factors of MS. Correlation of siMS score with PAI-1, microalbuminuria, homocysteine, indicates higher risk for progression of endothelial dysfunction and atherosclerosis with age. Abstract The flowers of Trollius species, named Jin Lianhua in Chinese, are widely used traditional Chinese herbs with vital biological activity that has been used for several decades in China to treat upper respiratory infections, pharyngitis, tonsillitis, and bronchitis. We developed a rapid and reliable method for simultaneous quantitative analysis of 19 flavonoids in trollflowers by using high-performance liquid

chromatography (HPLC). Chromatography was performed on Inertsil ODS-3 C18 column, with gradient elution methanol-acetonitrile-water with 0.02% (v/v) formic acid. Content determination was used to evaluate the quality of commercial trollflowers from different regions in China, while three *Trollius* species (*Trollius chinensis* Bunge, *Trollius ledebouri* Reichb, *Trollius buddae* Schipcz) were explicitly distinguished by using hierarchical clustering analysis. The linearity, precision, accuracy, limit of detection, and limit of quantification were validated for the quantification method, which proved sensitive, accurate and reproducible indicating that the proposed approach was applicable for the routine analysis and quality control of trollflowers. © 2013 Published by Elsevier B.V. Simultaneous multi-source and multi-temporal land cover classification using a compound maximum likelihood classifier

Item Type Conference Paper

Author M.S. Reis

Author L.V. Dutra

Author M.I.S. Escada

Abstract The most widely used change detection method is to classify remote sensing images independently for each date, and stack them to form a class sequence vector. However, impossible transitions within the sequences might occur and errors might be accumulated. To solve this, we propose a novel algorithm called Compound Maximum Likelihood (CML), based on the Maximum Likelihood classifier (ML). In CML information from all images is used jointly by considering the a priori probability of each class sequence. The algorithm was tested for Synthetic Aperture Radar and optical images classification in a study area in Pará state, within the Brazilian Amazon. CML presented either similar or very improved accuracy index values over ML land cover classifications. © 2017 National Institute for Space Research INPE. All Rights Reserved.

Single aflatoxin contaminated corn kernel analysis with fluorescence hyperspectral image

Item Type Conference Paper**Author** H. Yao**Author** Z. Hruska**Author** R. Kincaid**Author** A. Ononye**Author** R.L. Brown**Author** T.E. Cleveland

Abstract Aflatoxins are toxic secondary metabolites of the fungi *Aspergillus flavus* and *Aspergillus parasiticus*, among others. Aflatoxin contaminated corn is toxic to domestic animals when ingested in feed and is a known carcinogen associated with liver and lung cancer in humans. Consequently, aflatoxin levels in food and feed are regulated by the Food and Drug Administration (FDA) in the US, allowing 20 ppb (parts per billion) limits in food and 100 ppb in feed for interstate commerce. Currently, aflatoxin detection and quantification methods are based on analytical tests including thin-layer chromatography (TCL) and high performance liquid chromatography (HPLC). These analytical tests require the destruction of samples, and are costly and time consuming. Thus, the ability to detect aflatoxin in a rapid, nondestructive way is crucial to the grain industry, particularly to corn industry. Hyperspectral imaging technology offers a non-invasive approach toward screening for food safety inspection and quality control based on its spectral signature. The focus of this paper is to classify aflatoxin contaminated single corn kernels using fluorescence hyperspectral imagery. Field inoculated corn kernels were used in the study. Contaminated and control kernels under long wavelength ultraviolet excitation were imaged using a visible near-infrared (VNIR) hyperspectral camera. The imaged kernels were chemically analyzed to provide reference information for image analysis. This paper describes a procedure to process corn kernels located in different images for statistical training and classification. Two classification algorithms, Maximum Likelihood and Binary Encoding, were used to classify each corn kernel into "control" or "contaminated" through pixel classification. The Binary Encoding approach had a slightly better performance with accuracy equals to 87% or 88% when 20 ppb or 100 ppb was used as classification threshold, respectively. © 2010 Copyright SPIE - The International Society for Optical Engineering.

Abstract We propose a method to train a deterministic deep network for uncertainty quantification (UQ) with a single forward pass. Traditional Monte Carlo or ensemble based UQ methods largely leverage the variation of neural network weights to introduce uncertainty. We propose a hierarchical Gaussian mixture model (GMM) based nonlinear classifier to shape the extracted feature more flexibly and express the uncertainty by the entropy of the predicted posterior distribution. We perform large-scale training with this hierarchical GMM based loss function and introduce a natural gradient descent algorithm to update the parameters of the hierarchical GMM. With a single deterministic neural network, our uncertainty quantification approach performs well when training and testing on large datasets. We show competitive performance scores on several benchmark datasets and the out-of-distribution detection task on notable challenging dataset pairs such as CIFAR-10 vs. STL10/SVHN, and CIFAR100 vs. STL10/SVHN. © 2022, The Author(s), under exclusive license to Springer Nature Switzerland AG.

Single-step extraction & plasmonic sensing of sulphur in fuels using machine learning analysis of RGB images

Item Type Journal Article

Author D. Gallina

Author M.C. Valeriano

Author V.H. Paschoal

Author M.B. Mamián-López

Abstract Background: Mercaptans are compounds of great concern because they are one of the main sources of sulphur in fuels and can reduce engine performance. Diesel-biodiesel blends have partially replaced diesel fuel as part of efforts to promote greener energy. In Brazil, the current legislation permits up to 10 ppm of sulphur in diesel. Considering the impact of sulphur compounds produced within combustion engines, careful monitoring of fuels is essential to ensure a greener future, and methodologies to easily detect sulphur are needed, especially if they can be adapted for in situ measurements and are suitable for upcoming regulatory changes. Results: In this study, gold nanoparticles embedded in glycerol were used to extract, preconcentrate, and detect sulphur in biodiesel samples, with a mercaptan as sulphur source. The color changes due to nanoparticle aggregation were measured and processed using a smartphone app and machine learning to quantify sulphur. We demonstrate that this approach is suitable for determining this species in biodiesel at levels as low as 1.39 ppm, with the AuNPs@GLY-to-fuel ratio being easily adjustable, achieving lower limits of detection. Also, through SERS spectroscopy, we have demonstrated that the working principle behind the detection is the strong interaction between the thiol moiety and gold. This methodology can be easily customized, offering an interesting advantage from a practical perspective, as sulphur limit values vary worldwide and are influenced by the energy transition, which is a priority for public policies. Significance: The primary feature of our system is that it combines extraction, preconcentration, and sensing in a single step, eliminating the need for sample preparation or conditioning, and bringing the analysis to the field. The herein-developed sensor is low-cost, user-friendly, and can be customized and adapted to probe sulphur in commercial diesel, as verified here by SERS spectroscopy. © 2025 Elsevier B.V.

Abstract To address the challenge of explosive big data, distributed machine learning (ML) has drawn the interests of many researchers. Since many distributed ML algorithms trained by stochastic gradient descent (SGD) involve communicating gradients through the network, it is important to compress the transferred gradient. A category of low-precision algorithms can significantly reduce the size

of gradients, at the expense of some precision loss. However, existing low-precision methods are not suitable for many cases where the gradients are sparse and nonuniformly distributed. In this paper, we study is there a compression method that can efficiently handle a sparse and nonuniform gradient consisting of key-value pairs? Our first contribution is a sketch based method that compresses the gradient values. Sketch is a class of algorithms using a probabilistic data structure to approximate the distribution of input data. We design a quantile-bucket quantification method that uses a quantile sketch to sort gradient values into buckets and encodes them with the bucket indexes. To further compress the bucket indexes, our second contribution is a sketch algorithm, namely MinMaxSketch. MinMaxSketch builds a set of hash tables and solves hash collisions with a MinMax strategy. The third contribution of this paper is a delta-binary encoding method that calculates the increment of the gradient keys and stores them with fewer bytes. We also theoretically discuss the correctness and the error bound of three proposed methods. To the best of our knowledge, this is the first effort combining data sketch with ML. We implement a prototype system in a real cluster of our industrial partner Tencent Inc., and show that our method is up to $10\times$ faster than existing methods. © 2018 Association for Computing Machinery.

Sleep staging using cardiorespiratory signals

Item Type Journal Article

Author S.J. Redmond

Author P. De Chazal

Author C. O'Brien

Author S. Ryan

Author W.T. McNicholas

Author C. Heneghan

Abstract Question of study: We recently investigated the possibility of obtaining simplified Sleep- Wake-REM sleep stage information from subjects being assessed for Obstructive Sleep Apnea Syndrome (OSAS), using only electrocardiogram and respiration signals. The utility of such a system may be limited somewhat by the presence of OSAS in the patient group (in various degrees of severity). This study examines the effectiveness of such a system when applied to a subject group in which Sleep Disordered Breathing (SDB) is absent. Patients and methods: The study examined a database of 31 male subjects (Age = 42.0 ± 7.4 years, BMI = 30.7 ± 3.0 kg/m²). There was no significant presence of SDB in any of the subjects (AHI = 1.4 ± 1.2 events/h). A full polysomnography recording was obtained for each subject, including EEG, submental EMG and EOG for sleep staging. An automated sleep-staging system based solely on a single electrocardiogram signal and an inductance plethysmogram estimate of respiratory effort was developed. Features providing useful discrimination of sleep states were derived and the performance of both linear and quadratic discriminant classifiers were compared in correctly labeling 30-second epochs. The use of a time-dependent a priori probability in the classifier models was also investigated. Results: The best performance obtained was achieved by a linear discriminant classifier model using a time-dependent a priori probability. For a 3-class (W, S, R) system an agreement of $\kappa = 0.45$ was seen, which increases to $\kappa = 0.57$ when a simplified 2-class (W, S/R) system is considered. This corresponds to an epoch sleep-wake classification accuracy of 89%. Conclusions: Cardiorespiratory signals can provide sleep-wake staging accuracy which is comparable to actigraphy. Classification accuracy is not significantly altered by the presence or absence of sleep disturbed breathing. Cardiorespiratory-based sleep staging may be a useful addition to home sleep apnea monitoring systems. © 2007 Steinkopff-Verlag.

SMOTE: Synthetic minority over-sampling technique

Item Type Journal Article

Author N.V. Chawla

Author K.W. Bowyer

Author L.O. Hall

Author W.P. Kegelmeyer

Abstract An approach to the construction of classifiers from unbalanced datasets is described. A dataset is imbalanced if the classification categories are not approximately equally represented. Often real-world data sets are predominately composed of "normal" examples with only a small percentage of "abnormal" or "interesting" examples. It is also the case that the cost of misclassifying an abnormal (interesting) example as a normal example is often much higher than the cost of the reverse error. Under-sampling of the majority (normal) class has been proposed as a good means of increasing the sensitivity of a classifier to the minority class. This paper shows that a combination of our method of over-sampling the minority (abnormal) class and under-sampling the majority (normal) class can achieve better classifier performance (in ROC space) than only under-sampling the majority class. This paper also shows that a combination of our method of over-sampling the minority class and under-sampling the majority class can achieve better classifier performance (in ROC space) than varying the loss ratios in Ripper or class priors in Naive Bayes. Our method of over-sampling the minority class involves creating synthetic minority class examples. Experiments are performed using C4.5, Ripper and a Naive Bayes classifier. The method is evaluated using the area under the Receiver Operating Characteristic curve (AUC) and the ROC convex hull strategy. © 2002 AI Access Foundation and Morgan Kaufmann Publishers. Softmin discrete minimax classifier for imbalanced classes and prior probability shifts

Item Type Journal Article

Author C. Gilet

Author M. Guyomard

Author S. Destercke

Author L. Fillatre

Abstract This paper proposes a new approach for dealing with imbalanced classes and prior probability shifts in supervised classification tasks. Coupled with any feature space partitioning method, our criterion aims to compute an almost-Bayesian randomized equalizer classifier for which the maxima of the class-conditional risks are minimized. Our approach belongs to the historically well-studied field of randomized minimax criteria. Our new criterion can be considered as a self-sufficient classifier, or can be easily coupled with any pretrained Convolutional Neural Networks and Decision Trees to address the issues of imbalanced classes and prior probability shifts. Numerical experiments compare our criterion to several state-of-the-art algorithms and show the relevance of our approach when it is necessary to well classify the minority classes and to equalize the risks per class. Experiments on the CIFAR-100 database show that our criterion scales well when the number of classes is large. © 2023, The Author(s), under exclusive licence to Springer Science+Business Media LLC, part of Springer Nature.

Abstract Partial-label learning (PLL) is a peculiar weakly-supervised learning task where the training samples are generally associated with a set of candidate labels instead of single ground truth. While a variety of label disambiguation methods have been proposed in this domain, they normally assume a class-balanced scenario that may not hold in many real-world applications. Empirically, we observe degenerated performance of the prior methods when facing the combinatorial challenge from the long-tailed distribution and partial-labeling. In this work, we first identify the major reasons that the prior work failed. We subsequently propose SoLar, a novel Optimal Transport-based framework that allows to refine the disambiguated labels towards matching the marginal class prior distribution. SoLar additionally incorporates a new and systematic mechanism for estimating the long-tailed class prior distribution under the PLL setup. Through extensive experiments, SoLar exhibits substantially superior results on standardized benchmarks compared to the previous state-of-the-art PLL methods. Code and data are available at: <https://github.com/hbzju/SoLar>. © 2022 Neural information processing systems foundation. All rights reserved.

SPARSE JOINT SHIFT IN MULTINOMIAL CLASSIFICATION

Item Type Journal Article

Author D. Tasche

Abstract Sparse joint shift (SJS) was recently proposed as a tractable model for general dataset shift which may cause changes to the marginal distributions of features and labels as well as the posterior probabilities and the class-conditional feature distributions. Fitting SJS for a target dataset without label observations may produce valid predictions of labels and estimates of class prior probabilities. We present new results on the transmission of SJS from sets of features to larger sets of features, a conditional correction formula for the class posterior probabilities under the target distribution, identifiability of SJS, and the relationship between SJS and covariate shift. In addition, we point out inconsistencies in the algorithms which were proposed for estimating the characteristics of SJS, as they could hamper the search for optimal solutions, and suggest potential improvements. © 2024 American Institute of Mathematical Sciences. Spatial appreciation of the floor plan complexity in housing price appraisal

Item Type Journal Article

Author S. Bae

Author S. An
Author G. Choi
Author K. Ahn

Abstract This study explores the relationship between structural feature of apartment interiors and housing prices across four different regions. This study first constructs floor plan complexity indices based on Shannon entropy and Delentropy and compares both entropy measures in seizing structural complexity of images. Subsequently, we adopt sophisticated instruments to scrutinize the linear and nonlinear effects of floor plan complexity on housing prices. A series of hedonic price models and machine learning models with the SHapley Additive exPlanation are utilized in capturing the impacts and importance of floor plan complexity indices on housing prices. This study exhibits three notable findings: (1) Delentropy can serve as a useful tool for capturing the structural complexity of floor plan images due to its capability of considering the spatial distribution of pixels; (2) floor plan complexity is significantly and positively associated with housing prices across all the surveyed areas; and (3) the importance of floor plan complexity varies upon local contexts. Our study proposes a quantification method that fully represents the images into the numerical data to analyze the relationship between floor plans and housing prices. This methodological approach serves as a significant analytical tool for site selection, enabling more informed decision-making through comprehensive market analysis in the context of real estate development. From a long-term perspective, local governments can support efficient management for the sustainable development of the real estate market. © 2025 Elsevier Ltd.

Spatial context learning approach to automatic segmentation of pleural effusion in chest computed tomography images

Item Type Conference Paper

Author A. Mansoor

Author R. Casas

Author M.G. Linguraru

Editor Tourassi G.D.

Editor Armato S.G.

Abstract Pleural effusion is an abnormal collection of fluid within the pleural cavity. Excessive accumulation of pleural fluid is an important bio-marker for various illnesses, including congestive heart failure, pneumonia, metastatic cancer, and pulmonary embolism. Quantification of pleural effusion can be indicative of the progression of disease as well as the effectiveness of any treatment being administered. Quantification, however, is challenging due to unpredictable amounts and density of fluid, complex topology of the pleural cavity, and the similarity in texture and intensity of pleural fluid to the surrounding tissues in computed tomography (CT) scans. Herein, we present an automated method for the segmentation of pleural effusion in CT scans based on spatial context information. The method consists of two stages: first, a probabilistic pleural effusion map is created using multi-atlas segmentation. The probabilistic map assigns a priori probabilities to the presence of pleural uid at every location in the CT scan. Second, a statistical pattern classification approach is designed to annotate pleural regions using local descriptors based on a priori probabilities, geometrical, and spatial features. Thirty seven CT scans from a diverse patient population containing confirmed cases of minimal to severe amounts of pleural effusion were used to validate the proposed segmentation method. An average Dice coefficient of 0.82685 and Hausdorff distance of 16.2155 mm was obtained. © 2016 SPIE.

Spatial delineation of the compound flood transition zone using deep learning

Item Type Journal Article

Author F. Yarveysi

Author F.G. Diaz

Author H. Moftakhari

Author H. Moradkhani

Abstract Coastal and hydrologic floods are distinct yet interconnected phenomena, driven by oceanic and terrestrial processes, respectively. Their interaction—known as compound flooding—occurs when storm surge, heavy precipitation, and river flow coincide, significantly amplifying flood impacts in coastal riverine regions. These interactions give rise to a transition zone, where coastal and hydrologic flood processes converge, resulting in complex, prolonged inundation that is challenging to predict using traditional hydrodynamic models. Accurately delineating this zone is essential for improving flood risk assessment and mitigation strategies. In this study, we employ deep learning to quantify the relative contributions of terrestrial hydrologic and coastal flood drivers, enabling spatial delineation of the transition zone within Galveston Bay in Texas. This data-driven approach addresses the limitations of conventional models and supports more effective flood-resilience planning for vulnerable coastal communities. Our results reveal spatial patterns of flood driver dominance, with storm tide influencing coastal zones and river flow playing a greater role inland. The use of SHapley Additive exPlanations (SHAP) enables the delineation of a transition zone where no single driver dominates, underscoring the importance of compound flood modeling in such areas. This framework offers a scalable and interpretable solution for identifying high-risk zones, enhancing the precision of flood risk assessments, and informing targeted mitigation efforts in coastal regions. © 2025

Spatial Leakage in Classifying NASA FIRMS Thermal Anomalies as Wildfire Incidents: A Leakage-Controlled Evaluation of Radiometric, Temporal, and Spatiotemporal Features

Item Type Journal Article

Author A. Soltan

Author A. González-Martínez

Abstract NASA's Fire Information for Resource Management System (FIRMS) provides near-real-time thermal anomaly detections from VIIRS, but not all detections correspond to wildfire incidents: industrial heat, agricultural burning, and sensor artifacts produce false alarms that contribute to alert fatigue for emergency-management analysts. We study whether contextual machine learning (ML) features improve wildfire-incident classification from FIRMS detections, and—more importantly—whether reported gains survive leakage-controlled evaluation. We construct a labeled dataset by matching 521,395 VIIRS SNPP detections across CONUS in 2024 to 3766 NIFC

2024 wildfire perimeters, yielding 131,771 (25.3%) wildfire-matched and 389,624 candidate non-wildfire detections spanning 1067 distinct wildfire incidents. We benchmark five operational baselines and six classifiers under four validation regimes (random, event-aware, 5° spatial-block, and temporal holdout) with and without raw geographic coordinates. A naive random split inflates LightGBM to $F1 = 0.985$, but a leakage-controlled event-aware split reduces it to $F1 = 0.767$, and a spatial-block holdout to $F1 = 0.627$. Feature attribution shows geographic coordinates account for 88.9% of model gain—the summed share of LightGBM’s total split-gain attributed to the three coordinate features within the full-feature model; removing coordinates improves spatial-block generalization from $F1 = 0.627$ to 0.818, demonstrating that raw coordinates drive memorization of where 2024 fires occurred rather than transferable discrimination. We further show that spatiotemporal clustering must be causal: a model using full-partition clustering appears strong ($F1 = 0.908$) but leaks future detections, whereas a properly causal trailing-window version ties plain LightGBM in-distribution ($F1 = 0.762$). Combining causal clustering with no raw coordinates is the most robust configuration under spatial transfer (spatial-block $F1 = 0.868$ vs. 0.627 for the coordinate model). Bootstrap 95% confidence intervals show these gaps far exceed statistical uncertainty, and sensitivity analyses show the conclusions are robust to the spatial-block size and to the clustering-window choice. Under natural class prevalence (14%), precision falls to 0.69, and results are sensitive to the labeling buffer. All ML models nonetheless far exceed FIRMS high-confidence thresholding ($F1 = 0.128$). We argue that spatial leakage—not raw accuracy—is the central methodological issue for FIRMS wildfire-incident classification, and recommend coordinate-free, causal spatiotemporal-clustering features evaluated under spatial holdout. The system is intended as an analyst-prioritization decision-support layer, not autonomous incident confirmation. © 2026 by the authors.

Abstract DNA adducts and strand breaks are induced by various exogenous and endogenous agents. Accumulation of DNA damage is implicated in many disease processes, including cancer, aging, and neurodegeneration. The continuous acquisition of DNA damage from exogenous and endogenous stressors coupled with defects in DNA repair pathways contribute to the accumulation of DNA damage within the genome and genomic instability. While mutational burden offers some insight into the level of DNA damage a cell may have experienced and subsequently repaired, it does not quantify DNA adducts and strand breaks. Mutational burden also infers the identity of the DNA damage. With advances in DNA adduct detection and quantification methods, there is an opportunity to identify DNA adducts driving mutagenesis and correlate with a known exposome. However, most DNA adduct detection methods require isolation or separation of the DNA and its adducts from the context of the nuclei. Mass spectrometry, comet assays, and other techniques precisely quantify lesion types but lose the nuclear context and even tissue context of the DNA damage. The growth in spatial analysis technologies offers a novel opportunity to leverage DNA damage detection with nuclear and tissue context. However, we lack a wealth of techniques capable of detecting DNA damage in situ. Here, we review the limited existing in situ DNA damage detection methods and examine their potential to offer spatial analysis of DNA adducts in tumors or other tissues. We also offer a perspective on the need for spatial analysis of DNA damage in situ and highlight Repair Assisted Damage Detection (RADD) as an in situ DNA adduct technique with the potential to integrate with spatial analysis and the challenges to be addressed. © 2023 The Authors

Spatial structure characteristics detecting of landform based on improved 3D Lacunarity model

Item Type Journal Article

Author Y. Tao

Author G. Tang

Author J. Strobl

Abstract The spatial structure characteristics of landform are the foundation of geomorphologic classification and recognition. This paper proposed a new method on quantifying spatial structure characteristics of terrain surface based on improved 3D Lacunarity model. Lacunarity curve and its numerical integration are used in this model to improve traditional classification result that different morphological types may share the close value of indexes based on global statistical analysis. Experiments at four test areas with different landform types show that improved 3D Lacunarity model can effectively distinguish different morphological types per texture analysis. Higher sensitivity in distinguishing the tiny differences of texture characteristics of terrain surface shows that the quantification method by 3D Lacunarity model and its numerical integration presented in this paper could contribute to improving the accuracy of landform classifications and relative studies. © 2012 Science Press,

Spatial variation of waterborne Escherichia coli - Implications for routine water quality monitoring

Item Type Journal Article

Author R.S. Quilliam

Author K. Clements

Author C. Duce

Author S.B. Cottrill

Author S.K. Malham

Author D.L. Jones

Abstract Escherichia coli are often used as faecal indicator bacteria (FIB) to provide a measure of microbial pollution in recreational and shellfish harvesting waters. However, although model forecasts for predicting the concentrations of FIB in surface waters are becoming more robust, they suffer from an inconsistency in quantification methods and an understanding of the spatial variation of FIB within a water course.

The aim of this study was to investigate the transverse spatial variation in *E. coli* numbers (as an indicator of faecal pollution) across the estuary of the River Conwy, UK. Water samples were collected from four transverse transects across the estuary. Spatial variation of *E. coli* was significantly different from one side of the river to the other, although was not correlated with depth or the physiochemical properties of the water. Subsequently, microbial water quality classifications on the two opposite banks suggested very different levels of pollution coming down the river. This work has shown that the side of the river that routine water monitoring samples are taken from can make a significant difference to the classification of microbial water quality. This has important implications for sampling strategies and the use of microbial source tracking (MST) techniques. © IWA Publishing 2011.

Spatio-temporal contextual approaches to mapping land cover change based on remote sensing imagery

Item Type Conference Paper

Author J. Zhang

Author J. Zhang

Author Y. Tang

Author J. You

Abstract This paper explores data-driven methods for quantifying and incorporating spatio-temporal contextual information in the mapping of land cover change. In remote sensing, area classes of land cover are typically mapped via statistical manipulation of feature-space measurement, e.g., reflectance data, and other ancillary data. Contextual information has been known to have the potential of increasing the accuracy of land cover classification and change detection, on the ground that land cover often exhibits spatial and temporal correlations and, as such, should be properly accommodated. In Bayesian methods, a priori probabilities of class occurrences can be considered as contextual information, which are combined with class-conditional probability densities to arrive at discriminant decisions with minimized misclassification. These prior probabilities may be made to vary locally to honor variability in the strengths of spatial dependence in class occurrences. For deriving local prior joint probabilities in land cover co-occurrences over time, a modified Expectation and Maximization (EM) algorithm was developed, in which a local window size can be adjusted in the light of spatial dependences inferred from class probability densities computed from spectral data. Empirical studies were performed using bi-temporal Landsat TM image subsets in Wuhan, which confirmed the comparative benefits of incorporating localized prior probabilities in land cover change detection. © 2009 SPIE.

Spatio-Temporal Multi-Task Learning for Cardiac MRI Left Ventricle Quantification

Item Type Journal Article

Author S. Vesal

Author M. Gu

Author A. Maier

Author N. Ravikumar

Abstract Quantitative assessment of cardiac left ventricle (LV) morphology is essential to assess cardiac function and improve the diagnosis of different cardiovascular diseases. In current clinical practice, LV quantification depends on the measurement of myocardial shape indices, which is usually achieved by manual contouring of the endo- and epicardial. However, this process subjected to inter and intra-observer variability, and it is a time-consuming and tedious task. In this article, we propose a spatio-temporal multi-task learning approach to obtain a complete set of measurements quantifying cardiac LV morphology, regional-wall thickness (RWT), and additionally detecting the cardiac phase cycle (systole and diastole) for a given 3D Cine-magnetic resonance (MR) image sequence. We first segment cardiac LVs using an encoder-decoder network and then introduce a multitask framework to regress 11 LV indices and classify the cardiac phase, as parallel tasks during model optimization. The proposed deep learning model is based on the 3D spatio-temporal convolutions, which extract spatial and temporal features from MR images. We demonstrate the efficacy of the proposed method using cine-MR sequences of 145 subjects and comparing the performance with other state-of-the-art quantification methods. The proposed method obtained high prediction accuracy, with an average mean absolute error (MAE) of 129 mm², 1.23 mm, 1.76 mm, Pearson correlation coefficient (PCC) of 96.4%, 87.2%, and 97.5% for LV and myocardium (Myo) cavity regions, 6 RWTs, 3 LV dimensions, and an error rate of 9.0% for phase classification. The experimental results highlight the robustness of the proposed method, despite varying degrees of cardiac morphology, image appearance, and low contrast in the cardiac MR sequences. © 2013 IEEE.

Species-specific detection and quantification of common barnacle larvae from the Japanese coast using quantitative real-time PCR.

Item Type Journal Article**Author** N. Endo**Author** K. Sato**Author** K. Matsumura**Author** E. Yoshimura**Author** Y. Odaka**Author** Y. Nogata

Abstract Species-specific detection and quantification methods for barnacle larvae using quantitative real-time polymerase chain reaction (qPCR) were developed. Species-specific primers for qPCR were designed for 13 barnacle species in the mitochondrial 12S ribosomal RNA gene region. Primer specificity was examined by PCR using template DNA extracted from each of the 13 barnacle species, other unidentified

barnacle species, and field collected zooplankton samples. The resulting PCR products comprised single bands following agarose gel electrophoresis when the templates corresponded to primers. The amplifications were highly species-specific even for the field plankton samples. The field plankton samples were subjected to qPCR assay. The calculated DNA contents for each barnacle species were closely correlated with the number of larvae measured by microscopic examination. The method could be applied to quantify barnacle larvae in natural plankton samples.

Spectral-spatial classification of hyperspectral images via spatial translation-invariant wavelet-based sparse representation

Item Type Journal Article

Author L. He

Author Y. Li

Author X. Li

Author W. Wu

Abstract For hyperspectral image (HSI) classification, it is challenging to adopt the methodology of sparse-representation-based classification. In this paper, we first propose an ℓ_1 -minimization-based spectral-spatial classification method for HSIs via a spatial translation-invariant wavelet (STIW)-based sparse representation (STIW-SR), wherein both the spectrum dictionary and the analyzed signal are formed with STIW features. Due to the capability of a STIW to reduce both the observation noise and the spatial nonstationarity while maintaining the ideal spectra, which is proved with our signal-interference-noise spectrum model involved, it is expected that the pixels in the same class congregate in a lower dimensional subspace, and the separations among class-specific subspaces are enhanced, thus yielding a highly discriminative sparse representation. Then, we develop an approach to evaluate the sparsity recoverability of an ℓ_1 -minimization on HSIs in a probabilistic framework. This approach takes into account not only the recovery probability under the given support length of the ℓ_0 -norm solution but also the a priori probability of the support length; consequently, it overcomes the inability of traditional mutual/cumulative coherence conditions to address high-coherence HSIs. This paper reveals that the higher sparsity recoverability of a STIW-SR leads to its higher classification accuracy and that the increasing coherence does not necessarily lead to a reduced sparsity recovery probability, and this paper verifies the connection between ℓ_0 - and ℓ_1 -minimizations on HSIs. Experimental results from real-world HSIs suggest that our classification method significantly outperforms several representative spectral-spatial classifiers and support vector machines. © 1980-2012 IEEE.

Abstract A new approach to quantify the lung nodule speculation levels in CT (computed tomography) images was proposed. Firstly, two-dimensional image of nodule was generated by using the spiral scan technology. Secondly, the lung nodule was segmented in the two-dimensional image using the dynamic programming. Thirdly, based on the expanded regions from the segmented boundary, the speculation was segmented by use of threshold segmentation. Fourthly, the feature region where speculation may exist was extracted on the region of speculation boundary. Finally, the edge gradient orientation histogram as a new quantitative index was extracted to quantify the speculation levels of the lung nodule. The experimental results indicate that this index can quantify the speculation levels accurately with better classification results. © 2014 IEEE.

Abstract With the advent of biomarkers such as 11C-PIB and the increase in use of PET, automated methods are required for processing and analyzing datasets from research studies and in clinical settings. A common preprocessing step is the calculation of standardized uptake value ratio (SUVR) for inter-subject normalization. This requires segmented grey matter (GM) for VOI refinement. However 11C-PIB uptake is proportional to amyloid build up leading to inhomogeneities in intensities, especially within GM. Inhomogeneities present a challenge for clustering and pattern classification based approaches to PET segmentation as proposed in current literature. In this paper we modify a MR image segmentation technique based on expectation maximization for 11C-PIB PET segmentation. A priori probability maps of the tissue types are used to initialize and enforce anatomical constraints. We developed a Bézier spline based inhomogeneity correction techniques that is embedded in the segmentation algorithm and minimizes inhomogeneity resulting in better segmentations of 11C-PIB PET images. We compare our inhomogeneity with a global polynomial correction technique and validate our approach using co-registered MRI segmentations. © Springer-Verlag Berlin Heidelberg 2007.

Spring Festival and COVID-19 Lockdown: Disentangling PM Sources in Major Chinese Cities

Item Type Journal Article**Author** Q. Dai**Author** L. Hou**Author** B. Liu**Author** Y. Zhang

Author C. Song

Author Y. Feng

Abstract Responding to the 2020 COVID-19 outbreak, China imposed an unprecedented lockdown producing reductions in air pollutant emissions. However, the lockdown driven air pollution changes have not been fully quantified. We applied machine learning to quantify the effects of meteorology on surface air quality data in 31 major Chinese cities. The meteorologically normalized NO₂, O₃, and PM_{2.5} concentrations changed by −29.5%, +31.2%, and −7.0%, respectively, after the lockdown began. However, part of this effect was also associated with emission changes due to the Chinese Spring Festival, which led to ~14.1% decrease in NO₂, ~6.6% increase in O₃ and a mixed effect on PM_{2.5} in the studied cities that largely resulted from festival associated fireworks. After decoupling the weather and Spring Festival effects, changes in air quality attributable to the lockdown were much smaller: −15.4%, +24.6%, and −9.7% for NO₂, O₃, and PM_{2.5}, respectively. © 2021. Ssiqa: Multi-task learning for non-reference ct image quality assessment with self-supervised noise level prediction

Item Type Conference Paper

Author A.-A.-Z. Imran

Author D. Pal

Author B. Patel

Author A. Wang

Abstract Reduction of CT radiation dose is important due to the potential effects on patients. But lowering dose incurs degradation in the reconstructed image quality, furthering compromise in the diagnostic and image-based analyses performance. Considering the patient health risks, high quality reference images cannot be easily obtained, making the assessment challenging. Therefore, automatic no-reference image quality assessment is desirable. Leveraging an innovative self-supervised regularization in a convolutional neural network, we propose a novel, fully automated, no-reference CT image quantification method namely self-supervised image quality assessment (SSIQA). Extensive experimentation via in-domain (abdomen CT) and cross-domain (chest CT) evaluations demonstrates SSIQA is accurate in quantifying CT image quality, generalized across the scan types, and consistent with the established metrics and different relative dose levels. © 2021 IEEE.

Stacked Ensemble Learning with SHAP-Prioritized Intervention Ranking for Pavement Maintenance Automation

Item Type Journal Article

Author A. Gupta

Author P. Kumar

Abstract This study presents an automated decision-support framework for pavement maintenance and rehabilitation (M&R) prioritization using machine learning and explainable artificial intelligence (AI). A stacked ensemble classifier—combining tuned Light gradient boosting machine (LightGBM), ExtraTrees, support vector machine (SVM), and multilayer perceptron (MLP) as base learners with XGBoost as the meta-learner—was developed using nine pavement condition indicators with a dataset of 1166 points. The model predicts discrete M&R classes with strong predictive performance on the studied dataset, achieving an accuracy of 98.29%, macro F1-score of 0.98, precision of 0.963, and recall of 0.964. Model transparency was achieved through SHAP (SHapley Additive exPlanations), which identified Current million standard axles (MSA), Roughness International Roughness Index (IRI), and Structural Number as dominant predictors. A SHAP-informed composite scoring system enabled intra-class prioritization of road segments into Urgent, Medium, and Low categories. Sensitivity analysis confirmed that rankings for urgent interventions remained stable under $\pm 20\%$ feature contributions variations. The framework offers a robust and interpretable framework for network-level pavement management, supporting data-driven intervention planning with improved transparency and objectivity. © Chinese Society of Pavement Engineering 2026.

Staircase Network: structural language identification via hierarchical attentive units

Item Type Conference Paper

Author T.N. Trong

Author V. Hautamäki

Author K. Jokinen

Abstract Language recognition system is typically trained directly to optimize classification error on the target language labels, without using the external, or meta-information in the estimation of the model parameters. However labels are not independent of each other, there is a dependency enforced by, for example, the language family, which affects negatively on classification. The other external information sources (e.g. audio encoding, telephony or video speech) can also decrease classification accuracy. In this paper, we attempt to solve these issues by constructing a deep hierarchical neural network, where different levels of meta-information are encapsulated by attentive prediction units and also embedded into the training progress. The proposed method learns auxiliary tasks to obtain robust internal representation and to construct a variant of attentive units within the hierarchical model. The final result is the structural prediction of the target language and a closely related language family. The algorithm reflects a “staircase” way of learning in both its architecture and training, advancing from the fundamental audio encoding to the language family level and finally to the target language level. This process not only improves generalization but also tackles the issues of imbalanced class priors and channel variability in the deep neural network model. Our experimental findings show that the proposed architecture outperforms the state-of-the-art i-vector approaches on both small and big language corpora by a significant margin. © ODYSSEY 2018. Standardized and semiautomated workflow for 3D characterization of liberated particles

Item Type Journal Article

Author S. Gupta

Author J.R. da Assuncao Godinho

Author K. Gotkowski

Author F. Isensee

Abstract MSPaCMAN is the recently developed workflow that does the mineralogical quantification of individual particles using its histograms while considering the effects of partial volume artefacts in interphases at particle level detail. This paper demonstrates and validates the new developments in the MSPaCMAN workflow, aiming to minimize user bias and enhance the accuracy of MSPaCMAN. Here, in the new developments of MSPaCMAN workflow, firstly, the recently developed deep learning method, namely ParticleSeg3D, is employed to distinguish particles from the background. Secondly, the particle's size and shape information are considered along with its histogram to classify and quantify the mineral phases in liberated particles. After the new developments, the detection limit of MSPaCMAN to characterize small and thin liberated particles is enhanced. Experimental results demonstrate the effectiveness of the MSPaCMAN's updated workflow. It was found that the mineralogical composition calculated by the MSPaCMAN's updated workflow was precise, with the highest coefficient of variance of 6.56%. Moreover, the mineralogical composition determined by MSPaCMAN's updated workflow had low

variance across three different reconstruction parameters and two different voxel sizes (5.5 μm and 10 μm). Comparisons with other quantification methods highlight the accuracy of MSPaCMan's updated workflow to determine the mineralogical compositions. When analyzing a test sample consisting of quartz, calcite, fluorite, and lepidolite, MSPaCMan's updated workflow achieved the highest mineralogical deviation of only 7.73% from the reference mineralogy. In contrast, the random forest algorithm resulted in a deviation of 51.47%, while the manual thresholding method yielded a deviation of 41.46%. Overall, these findings emphasize the reliability and accuracy of MSPaCMan's updated workflow in quantifying mineralogical composition. © 2023

Abstract Background - A number of medications such as beta-blockers, ACE-inhibitors, angiotensin receptor blockers and aldosterone antagonists, improve survival in patients with heart failure (HF) and reduced ejection fraction. No therapy has been proved to be beneficial for patients with heart failure and preserved ejection fraction (PLVEF). Objectives - The aim of the study was to assess the effect of statin therapy on all-cause mortality and cardiovascular rehospitalization rate in patients with HF and PLVEF during one-year follow-up. Methods - We evaluated 146 patients with HF and PLVEF (ejection fraction $\geq 45\%$). Patients were divided into the statin therapy group ($n = 103$, mean age 69 ± 11 y, 52 men) and the group without statins ($n = 43$, mean age 66 ± 16 y, 25 men). We analysed the effects of the statin treatment prescribed to patients at discharge. Patients were followed up for one year. Results - The age, gender, NYHA functional class, prevalence of co-morbidities (renal dysfunction, COPD, diabetes mellitus) did not differ between the groups ($P = \text{NS}$). Patients receiving statin therapy more frequently had an ischaemic aetiology of HF (79% vs. 39.5%; $P < 0.001$) and hypertension (76% vs. 58%; $P < 0.05$). No differences in ejection fraction were observed neither by echocardiography (58% vs. 55%; $P = \text{NS}$) nor by basic laboratory data. Patients who received statins were often additionally treated with beta-blockers (91% vs. 70%; $P < 0.005$), aspirin (77 vs. 44%; $P < 0.01$), thienopyridines (22% vs. 5%; $P < 0.01$) and less frequently with oral anticoagulants (5% vs. 23%; $P < 0.005$). In the group receiving statins a significantly lower mortality (4% vs. 21%; $P < 0.001$) and rehospitalization rate (43% vs. 69%; $P < 0.05$) was documented. After adjustment for all univariate predictors of the occurrence of study primary end-points, statin therapy was shown to be associated with significant and independent reduction in all-cause mortality ($\text{HR} = 0.24$ [95%CI: 0.07 - 0.90] $P < 0.05$) and cardiovascular rehospitalization rate ($\text{HR} = 0.55$ [95%CI: 0.33 - 0.92] $P < 0.05$). After propensity matching statin therapy remained an independent factor reducing one-year mortality rate ($\text{HR} = 0.11$ [95%CI: 0.01 - 0.99] $P < 0.05$). Conclusions - This study showed that statin therapy may have beneficial effects on mortality and rehospitalization rates among patients with HF and PLVEF. It also suggests a potential role for statins as a new therapeutic option in patients with HF and PLVEF, but these observations need to be confirmed in large randomized trials.

Statistical 3D object classification and localization with context modeling

Item Type Conference Paper

Author M. Grzegorzek

Author E. Izquierdo

Abstract This contribution presents a probabilistic approach for automatic classification and localization of 3D objects in 2D multi-object images taken from a real world environment. In the training phase, statistical object models and statistical context models are learned separately. For the object modeling, the recognition system extracts local feature vectors from training images using the wavelet transformation and models them statistically by density functions. Since in contextual environments a-priori probabilities for occurrence of different objects cannot be assumed to be equal, statistical context modeling is introduced in this work. The a-priori occurrence probabilities are learned in the training phase and stored in so-called context models. In the recognition phase, the system determines the unknown number of objects in a multi-object scene first. Then, the object classification and localization are performed. Recognition results for experiments made on a real dataset with 3240 test images compare the performance of the system with and without consideration of the context modeling. © 2007 EURASIP.

Statistical analysis to assess automated level of suspicion scoring methods in breast ultrasound

Item Type Conference Paper

Author M. Galperin

Abstract A well-defined rule-based system has been developed for scoring 0-5 the Level of Suspicion (LOS) based on qualitative lexicon describing the ultrasound appearance of breast lesion. The purposes of the research are to asses and select one of the automated LOS scoring quantitative methods developed during preliminary studies in benign biopsies reduction. The study has used Computer Aided Imaging System (CAIS) to improve the uniformity and accuracy of applying the LOS scheme by automatically detecting, analyzing and comparing breast masses. The overall goal is to reduce biopsies on the masses with lower levels of suspicion, rather that increasing the accuracy of diagnosis of cancers (will require biopsy anyway). On complex cysts and fibroadenoma cases experienced radiologists were up to 50% less certain in true negatives than CAIS. Full correlation analysis was applied to determine which of the proposed LOS quantification methods serves CAIS accuracy the best. This paper presents current results of applying statistical analysis for automated LOS scoring

quantification for breast masses with known biopsy results. It was found that First Order Ranking method yielded most the accurate results. The CAIS system (Image Companion®, Data Companion® software) is developed by Almen Laboratories and was used to achieve the results.

Statistical analysis, machine learning modeling, and text analytics of aggregation attachment efficiency: Mono and binary particle systems

Item Type Journal Article

Author A. Gomez-Flores

Author S.A. Bradford

Author G. Hong

Author H. Kim

Abstract The aggregation attachment efficiency (α) is the fraction of particle–particle collisions resulting in aggregation. Despite significant research, α predictions have not accounted for the full complexity of systems due to constraints imposed by particle types, dispersed matter, water chemistry, quantification methods, and

modeling. Experimental α values are often case-specific, and simplified systems are used to rule out complexity. To address these challenges, statistical analysis was performed on α databases to identify gaps in current knowledge, and machine learning (ML) was used to predict α under various particle types and conditions. Moreover, text analytics was employed to support knowledge from statistics and ML, as well as gain insight into the ideas communicated by current literature. Most studies investigated α in mono-particle systems, but binary or higher systems require more investigation. Furthermore, our work highlights that numerous variables, interactions, and mechanisms influence α behavior, making its investigation complex and difficult for both experiments and modeling. Consequently, future research should incorporate more particle types, shapes, coatings, and surface heterogeneities, and aim to address overlooked variables and conditions. Therefore, building a comprehensive α database can enable the development of more accurate empirical models for prediction. © 2023 Elsevier B.V.

Statistical and wavelet based texture features for fish oocytes classification

Item Type Conference Paper

Author E. González-Rufino

Author P. Carrión

Author A. Formella

Author M. Fernández-Delgado

Author E. Cernadas

Abstract The study of biology and population dynamics of fish species requires the estimation of fecundity parameters in individual fish in many fisheries laboratories. The traditional procedure used in fisheries research is to classify and count the oocytes manually on a subsample of known weight of the ovary, and to measure few oocytes under a binocular microscope. With an adequate interactive tool, this process might be done on a computer. However, in both cases the task is very time consuming, with the obvious consequence that fecundity studies are not conducted routinely. In this work we develop a computer vision system for the classification of oocytes using texture features in histological images. The system is structured in three stages: 1) extraction of the oocyte from the original image; 2) calculation of a texture feature vector for each oocyte; and 3) classification of the oocytes using this feature vector. A statistical evaluation of the proposed system is presented and discussed. © 2011 Springer-Verlag.

Statistical classification of buried unexploded ordnance using nonparametric prior models

Item Type Journal Article

Author A. Aliamiri

Author J. Stalnaker

Author E.L. Miller

Abstract We used kernel density estimation (KDE) methods to build a priori probability density functions (pdfs) for the vector of features that are used to classify unexploded ordnance items given electromagnetic-induction sensor data. This a priori information is then used to develop a new suite of estimation and classification algorithms. As opposed to the commonly used maximumlikelihood parameter estimation methods, here we employ a maximum a posteriori (MAP) estimation algorithm that makes use of KDE-generated pdfs. Similarly, we use KDE priors to develop a suite of classification schemes operating in both "feature" space as well as "signal/data" space. In terms of feature-based methods, we construct a support vector machine classifier and its extension to support M-ary classification. The KDE pdfs are also used to synthesize a MAP feature-based classifier. To address the numerical challenges associated with the optimal data-space Bayesian classifier, we have used several approximation techniques, including Laplacian approximation and generalized likelihood ratio tests employing the priors. Using both simulations and real field data, we observe a significant improvement in classification performance due to the use of the KDE-based prior models. © 2007 IEEE.

Abstract Open-world object detection (OWOD) has recently obtained significant interest due to its practical applications. The core issue lies in a model's ability to identify new object categories and incrementally acquire knowledge about them, all while retaining information about previously learned classes. Prior solutions have typically relied on either strong or weak supervision for the novel-class (i.e., out-of-distribution) data during detection, an approach that might not be applicable in real-world scenarios. This paper constructs a new setup where novel classes are only encountered on the fly at the inference stage. In response to this challenge, an innovative OWOD detector is tailored for the open-set incremental learning environment. The proposed methodology incorporates label smoothing as a mechanism to prevent the detector from prematurely and confidently assigning novel classes to existing categories, thereby facilitating the discovery of novel classes. Extensive experiments conducted on our realistic setup demonstrate the efficacy of our method for discovering novel classes in the new setup. © The Author(s), under exclusive license to Springer Nature Singapore Pte Ltd. 2025.

Stochastic Binary Network for Universal Domain Adaptation

Item Type Conference Paper
Author S.K. Jain
Author S. Das
Abstract Universal domain adaptation (UniDA) is the unsupervised domain adaptation with label shift. UniDA aims to classify unlabeled target samples into one of the "known" categories or into a single "unknown" category. Its main challenge lies in detecting private classes from both domains and performing alignment between the common classes. Current methods employ various techniques and loss functions to address these challenges. However, these methods commonly represent classifiers as point weight vectors, which are prone to overfitting by the source domain samples due to the lack of supervision from the target domain.

Consequently, these classifiers struggle to separate target samples into known and unknown categories effectively. To address this, we introduce a novel framework called Stochastic Binary Network for Universal Domain Adaptation (STUN). STUN uses a Stochastic binary classifier for each class, whose weight is modeled as Gaussian distribution, enabling to sample an arbitrary number of classifiers while keeping the model size same as of two classifiers. Consistency between these sampled classifiers is used to derive the confidence scores for both source and target samples, which facilitates the alignment of common classes using weighted adversarial learning. Finally, we use deep discriminative clustering to formulate a loss function for solving the problem of fragmented feature distributions in the target domain. Extensive ablation studies and state-of-the-art results across three standard benchmark datasets show the efficacy of our framework. © 2024 IEEE.

Stochastic modeling of group testing with random total sample size

Item Type Journal Article

Author B. Mohammed

Author A. Sghir

Author S. El Idrissi

Author A. Maleb

Abstract In the classical Dorfman group testing procedure Dorfman (1943), a fixed population of size N is divided into k pools of equal size n [jls-end-space/]. Each pool is tested: a negative result clears all n individuals, whereas a positive result triggers individual testing within the pool. Put (Formula presented) where p denotes the infection prevalence and q_n is the probability that a pool is positive under perfect classification. The expected number of tests, denoted by XN [jls-end-space/], is given by (Formula presented) However, most applied presentations focus mainly on the expected number of tests and do not quantify the stochastic risk of exceeding a finite laboratory capacity when the number of pools, the total sample size, or the diagnostic accuracy is uncertain. This gap is important for operational screening programs, where a design that is optimal in expectation may still overload the laboratory with non-negligible probability. First, this paper investigates the distribution of XN [jls-end-space/], allowing us to derive the threshold probability (Formula presented) for exceeding a given testing capacity x [jls-end-space/]. Second, we further extend the model by considering random population sizes N and incorporating test misclassification through sensitivity (Formula presented) and specificity (Formula presented). In this setting, (Formula presented) We also add variance formulae, a normal tail approximation, a pool-size-dependent sensitivity (Formula presented), and a Monte Carlo validation showing that the analytical formulae match simulated operating characteristics. © 2026 Published by Elsevier B.V. Stochastic seismic inversion and Bayesian facies classification applied to porosity modeling and igneous rock identification

Item Type Journal Article

Author F.J.D. Fernandes

Author L. Teixeira

Author A.F.M. Freire

Author W.M. Lupinacci

Abstract We apply stochastic seismic inversion and Bayesian facies classification for porosity modeling and igneous rock identification in the presalt interval of the Santos Basin. This integration of seismic and well-derived information enhances reservoir characterization. Stochastic inversion and Bayesian classification are powerful tools because they permit addressing the uncertainties in the model. We used the ES-MDA algorithm to achieve the realizations equivalent to the percentiles P10, P50, and P90 of acoustic impedance, a novel method for acoustic inversion in presalt. The facies were divided into five: reservoir 1, reservoir 2, tight carbonates, clayey rocks, and igneous rocks. To deal with the overlaps in acoustic impedance values of facies, we included geological information using a priori probability, indicating that structural highs are reservoir-dominated. To illustrate our approach, we conducted porosity modeling using facies-related rock-physics models for rock-physics inversion in an area with a well drilled in a coquina bank and evaluated the thickness and extension of an igneous intrusion near the carbonate-salt interface. The modeled porosity and the classified seismic facies are in good agreement with the ones observed in the wells. Notably, the coquinas bank presents an improvement in the porosity towards the top. The a priori probability model was crucial for limiting the clayey rocks to the structural lows. In Well B, the hit rate of the igneous rock in the three scenarios is higher than 60%, showing an excellent thickness-prediction capability. © 2023 The Authors

Stochastic variational inference improves quantification of multiple timepoint arterial spin labelling perfusion MRI

Item Type Journal Article

Author T.F. Kirk

Author G.G. Kenyon

Author M.S. Craig

Author M.A. Chappell

Abstract Multiple-timepoint arterial spin labelling MRI is a non-invasive imaging technique that permits measurement of both cerebral blood flow and arterial transit time, the latter of which is an emerging biomarker of interest for cerebrovascular health. Quantification of arterial spin labelling data is challenging due to the low signal to noise ratio and non-linear tracer kinetics of this technique. In this work, we introduce a new quantification method called SSVB that addresses limitations in existing methods and demonstrate its performance using simulations and acquisition data. Simulations showed that the method is more accurate, particularly for estimating arterial transit time, and more robust to noise than existing techniques. On high spatial resolution data acquired at 3 T, the method produced less noisy parameter maps than the comparator method and captured greater variation in arterial transit time on a cross-sectional cohort. Strain ratio vs strain histogram for the elastographic evaluation of non-calcific chronic pancreatitis (CP) — A prospective, single-center, comparative study

Item Type Journal Article

Author Y.D. Nova

Author J.E. Domínguez Muñoz

Author J. Lariño-Noia

Author P. Míguez-Sánchez

Author J. Iglesias-García

Abstract Introduction: diagnosis of chronic pancreatitis (CP) at early stages remains challenging. Endoscopic ultrasound (EUS) guided strain elastography (SE) has improved the diagnostic yield of CP. The aim of our study was to evaluate the diagnostic yield of SE quantification methods, strain ratio (SR) and strain histogram (SH) to detect non-calcific CP. Methods: a prospective, comparative study was performed with patients undergoing EUS-guided SE for non-calcific CP evaluation. Procedures were performed with linear echoendoscopes. The number of EUS criteria

according to the Rosemont classification were evaluated. SH analysis targeted the pancreatic body area, while SR compared this area (A) to a soft extrapancreatic reference area (B), using B/A as the final ratio. Data are shown as percentages and means (95 % CI) and analyzed using ANOVA, linear regression and Spearman tests. Diagnostic accuracy of SR and SH were evaluated using the Rosemont classification as a reference. STARD criteria were followed. Results: two hundred and eighty-four patients were included (mean age 49.8 years, range 17-85; 142 males). Among them, 43 (15.1 %) had a normal pancreas, 110 (38.7 %) had indeterminate findings, and 131 (46.1 %) had findings suggestive of CP. A SR > 2.42 had a 91.7 % sensitivity and 88.1 % specificity (ROC = 0.968). An SH < 116.1 had an 88.0 % sensitivity and 97.7 % specificity (ROC = 0.964). EUS criteria correlated with pancreatic fibrosis severity by SR ($r = 0.785$, $p < 0.0001$) and SH ($r = -0.742$, $p < 0.0001$). Age correlated with EUS criteria ($r = 0.127$, $p = 0.03$) but not with SE. Conclusions: the quantification of the degree of pancreatic fibrosis by SR and SH during pancreatic EUS-guided SE had a high diagnostic accuracy for CP and was not influenced by age. © Copyright 2026 y Creative Commons (CC-BY-NC-ND). Straw-Derived Biochar Alters Soil Phosphorus Availability and Inorganic Phosphorus Fractions: A Global Synthesis

Item Type Journal Article

Author J. Xu

Author S. Liu

Author C. Liang

Author H. Liu

Author Y. Liu

Abstract Straw-derived biochar is increasingly used for residue recycling and soil fertility improvement, but its effects on soil inorganic phosphorus (P) fractions and their relationships with available P (AP) remain unclear. Here, we synthesized 1170 paired observations from 51 studies using meta-analysis, partial least squares path modeling, and machine learning to quantify straw biochar effects on soil AP, inorganic P fractions, microbial biomass P (MBP), and phosphatase activities, and to identify important variables related to these responses. Straw biochar increased soil AP by 77.0% and altered the distribution of inorganic P fractions. The relationships between inorganic P fractions and AP differed: Fe-bound P and occluded P showed positive and negative associations with AP, respectively, whereas Ca-bound P and Al-bound P showed no significant associations with AP. Fe-bound P and Al-bound P increased more strongly in soils with low initial AP, while higher biochar total P corresponded to weaker Fe-bound P accumulation but greater Ca-bound P accumulation. Straw biochar showed a positive response in MBP, while acid and neutral phosphatase activities showed decreasing trends, suggesting distinct microbial P cycling responses involving changes in microbial biomass P and phosphatase activities. These findings provide a P-fraction perspective for evaluating straw biochar as a site-specific amendment for soil P management. © 2026 by the authors.

Strawberry Fruit Deformity Detection and Symmetry Quantification Using Deep Learning and Geometric Feature Analysis

Item Type Journal Article**Author** L. Jiang**Author** Y. Wang**Author** H. Yan**Author** Y. Yin**Author** C. Wu

Abstract The external appearance of strawberry fruits serves as a critical criterion for their commercial value and grading standards. However, current research primarily emphasizes ripeness and surface defects, with limited attention given to the quantitative analysis of geometric characteristics such as deformity and symmetry. To address this gap, this study proposes a comprehensive evaluation framework that integrates deep learning-based segmentation with geometric analysis for strawberry appearance quality assessment. First, an enhanced YOLOv11 segmentation model incorporating a Squeeze-and-Excitation attention mechanism was developed to enable high-precision extraction of individual fruits, achieving Precision, Recall, AP50, and F1 scores of 91.11%, 87.46%, 92.90%, and 88.45%, respectively. Second, a deformity quantification method was designed based on the number of deformity points (Nd), deformity rate (Rd), and spatial distance metrics (Gmin and Gmax). Experimental results demonstrated significant differences in Rd and Gmax between deformed and normal strawberries, indicating strong classification capability. Finally, principal component analysis (PCA) was employed to extract the primary axis direction, and morphological symmetry was quantitatively evaluated using Intersection over Union (IoU) and Area Difference Ratio (AreaD_Ratio). The results revealed that most samples fell within an IoU range of 0.6–0.8 and AreaD_Ratio below 0.4, indicating noticeable inter-individual differences in fruit symmetry. This study aims to establish a three-stage analytical framework—segmentation, deformity quantification, and symmetry evaluation—for assessing strawberry appearance quality, with the goal of supporting key applications in automated grading and precision quality inspection. © 2025 by the authors.

Strengthening Machine Learning Reproducibility for Image Classification

Item Type Journal Article

Author G. Shao

Author H. Zhang

Author J. Shao

Author K. Woeste

Author L. Tang

Abstract Machine learning (ML) reproducibility needs to be informed with reliable evaluation measures. However, routine image classification is evaluated using metrics that are highly sensitive to class prevalence. Consequently, the reproducibility of ML models remains unclear due to class imbalance-induced noise. We suggest regularly using class imbalance-resistant evaluation metrics, including balanced accuracy, area under precision-recall curve, and image classification efficacy, for the evaluation of the reproducibility of ML models. Each of these evaluation metrics is conceptually consistent with and logically complements the others, and their joint use can help explain different aspects of classification performance at the whole-class level and individual class level. These metrics can be used for the validation, testing, and/or transfer of ML classifiers. Comprehensive analysis using these metrics as a routine approach strengthens the reproducibility of ML models. © Guofan Shao, et al.

Structural Factor Analysis of Lexical Complexity Constructs and Measures: A Quantitative Measure-Testing Process on Specialised Academic Texts

Item Type Journal Article

Author M. Nasser

Author P. McCarthy

Abstract This study evaluates 22 lexical complexity measures that represent the three constructs of density, diversity and sophistication. The selection of these measures stems from an extensive review of the SLA linguistics literature. All measures were subjected to qualitative screening for indicators/predictors of lexical proficiency/development and criterion validity based on the body of scholarship. This study's measure-testing process begins by dividing the selected measures into two groups, similarly calculated and dissimilarly calculated, based on their quantification methods and the results of correlation tests. Using a specialized corpus of postgraduate academic texts, a Structural Factor Analysis (SFA) comprising a Confirmatory Factor Analysis (CFA) and Exploratory Factor Analysis (EFA) is then conducted. The purpose of SFA is to 1) verify and examine the lexical classifications proposed in the literature, 2) evaluate the relationship between various lexical constructs and their representative measures, 3) identify the indices that best represent each construct and 4) detect possible new structures/dimensions. Based on the analysis of the corpus, the study discusses the construct-distinctiveness of lexical complexity constructs, as well as strong indicators of each conceptual/mathematical group among the measures. Finally, a unique and smaller set of measures representative of each construct is suggested for future studies that require measure selection. © 2023 Informa UK Limited, trading as Taylor & Francis Group.

Study of the effects of mineral salts on the biofilm formation on polypropylene fibers using three quantification methods

Item Type Journal Article

Author L. Bystrianský

Author M. Hujslová

Author M. Gryndler

Abstract The microbial biofilms are ubiquitous in nature and represent important biological entities that affect various aspects of human life. As such, they attracted considerable attention during last decades, with the factors affecting the biofilm development being among the frequently studied topics. In our work, the biofilm was cultivated on the surface of polypropylene fibers in a nutrient medium inoculated by the suspension of two unsterile soils. The effects of ionic strength and valence of salt on the amount of the produced biofilm and on composition of biofilm microbial communities were investigated. The effect of valence was significant in some OTUs: *Arthrobacter*/*Pseudarthrobacter*/*Paenarthrobacter* and *Bacillus* with positive response to monovalent salt (KCl) and *Streptomyces*, *Lysinibacillus*, *Pseudomonas*, and *Ensifer* with positive response to divalent salt (MgSO₄). The significant preference for a certain concentration of salts was observed in the case of OTUs *Agrobacterium*, *Bacillus* (both 100 mM), and *Brevundimonas* (30 mM). A new quantification method based on measuring of oxidizable organic carbon in biofilm biomass, based on dichromate oxidation, was used. We compared the results obtained using this method with results of crystal violet destaining and measuring of extracted DNA

concentration as proxies of the biofilm biomass. The dichromate oxidation is simple, inexpensive, and fast, and our results show that it may be more sensitive than crystal violet destaining. The highest biomass values tended to associate with high concentrations of the divalent salt. This trend was not observed in treatments where the monovalent salt was added. Our data confirm the importance of inorganic ions for biofilm composition and biomass accumulation. © 2020, Institute of Microbiology, Academy of Sciences of the Czech Republic, v.v.i.

Study on deep learning methods for coal burst risk prediction based on mining-induced seismicity quantification

Item Type Journal Article

Author X. Cheng

Author W. Qiao

Author H. He

Abstract The assessment of Coal burst risk (CBR) is the premise of bump disaster prevention and control. It is the implementation criterion to guide various rock burst prevention and control measures. The existing static prediction and evaluation methods for CBR cannot be effectively combined with the results of underground dynamic monitoring. This study proposed a mining-induced seismicity information quantification method based on the fractal theory. Deep learning methods were used to construct a deep learning framework of coal burst risk (DLFR) based on the fractal dimension of microseismic information. Gray correlation analysis (GRA), information gain ratio (IGR), and Pearson correlation coefficient are used to screen and compare factors. Statistical evaluation indicators such as macro-F1, accuracy rate, and fitness curve were used to evaluate model performance. Taking the Gaojiapu coal mine as a case study, the performance of deep learning models such as BP Neural Network (BP), Support Vector Machine (SVM) and its optimized model based on particle swarm optimization (PSO) algorithm under this framework is discussed. The research results' reliability and validity are verified by comparing the predicted results with the actual results. The research results show that the prediction results of CBR in DLFR are consistent with the actual results, and the model is reliable and effective. The mining-induced seismicity quantification can solve the problem of insufficient training samples for the CBR. With this, different pressure relief measures can be formulated based on the results of the CBR predictions to achieve "graded" precise prevention and control. © 2023, The Author(s).

Abstract Background: Transcriptome expression studies identified distinct muscle invasive bladder cancer (MIBC) subtypes closely related with breast cancer subclasses. Here we developed a sensitive quantification method for MIBC subclassification (luminal, basal, p53-like). In addition, the subtype specific expression of drug targets has been investigated. Methods: Absolute quantification (nCounter) of a 64-gene panel was performed on MIBC patients (n=47) treated exclusively with radical cystectomy (RC). In conjunction of 170 MIBCs from 3 independent cohorts, a minimal set of consensus genes has been established. Survival of the consensus subtypes has been assessed by multivariate analysis. Relevant drug targets were tested for their subtype specificity in a clustering independent assessment. Results: A reduced 36-gene panel stably clustered into 3 subtypes throughout the cohorts (luminal, basal, infiltrated). Patients treated by RC only, showed worst 8-year disease specific survival (DSS) for the luminal subtype in contrast to the infiltrated subtype (17% vs. 73%, p=0.011). In multivariate analyses, the risk stratification based on luminal versus not-luminal MIBC proved to be an independent predictor for DSS superior to the TNM system in patients with RC. Drug targets (e.g. ERBB2, FGFR, AR, PDGFRB) showed a distinct subtype attribution. The subtypes based on this nCounter screening could further be validated by the TCGA cohort. Conclusion: This MIBC subtype screening predicted survival and allowed an analysis of subtype specific drug targets, thus being a powerful tool for the translation of personalized MIBC treatment concepts. © Rinaldetti et al.

Subspace learning via local probability distribution for hyperspectral image classification

Item Type Journal Article

Author H. Luo

Author Y.Y. Tang

Author L. Yang

Abstract The computational procedure of hyperspectral image (HSI) is extremely complex, not only due to the high dimensional information, but also due to the highly correlated data structure. The need of effective processing and analyzing of HSI has met many difficulties. It has been evidenced that dimensionality reduction has been found to be a powerful tool for high dimensional data analysis. Local Fisher's liner discriminant analysis (LFDA) is an effective method to treat HSI processing. In this paper, a novel approach, called PD-LFDA, is proposed to overcome the weakness of LFDA. PD-LFDA emphasizes the probability distribution (PD) in LFDA, where the maximum distance is replaced with local variance for the construction of weight matrix and the class prior probability is applied to compute the affinity matrix. The proposed approach increases the discriminant ability of the transformed features in low dimensional space. Experimental results on Indian Pines 1992 data indicate that the proposed approach significantly outperforms the traditional alternatives. © 2015 Huiwu Luo et al.

SUN: Stochastic UNSupervised Learning for Data Noise and Uncertainty Reduction

Item Type Journal Article

Author N. Christakis

Author D. Drikakis

Abstract Unsupervised learning methods significantly benefit various practical applications by effectively identifying intrinsic patterns within unlabelled data. However, inherent data noise and uncertainties often compromise model reliability, result interpretability, and the overall effectiveness of unsupervised learning strategies, particularly in complex fields such as biomedical, engineering, and physics research. To address these critical challenges, this study proposes SUN (Stochastic UNsupervised learning), a novel approach that integrates probabilistic unsupervised techniques—specifically Gaussian Mixture Models—into the RUN-ICON unsupervised learning algorithm to achieve optimal clustering, systematically reduce data noise, and quantify inherent uncertainties. The SUN methodology strategically leverages probabilistic modelling for robust classification and detection tasks, explicitly targeting particle dispersion scenarios related to environmental pollution and airborne viral transmission, with implications for minimising public health risks. By combining advanced uncertainty quantification methods and innovative unsupervised denoising techniques, the proposed study aims to provide more reliable and interpretable insights than conventional methods while alleviating issues such as computational complexity and reproducibility that limit traditional mathematical modelling. This research contributes to enhanced trustworthiness and interpretability of unsupervised learning systems, offering a robust methodological framework for handling significant uncertainty in complex real-world data environments. © 2025 by the authors.

Supervised learning to quantify amyloidosis in whole brains of an alzheimer's disease mouse model acquired with optical projection tomography

Item Type Journal Article**Author** D. Nguyen**Author** V. Uhlmann**Author** A.L. Planchette**Author** P.J. Marchand**Author** D. Van De Ville**Author** T. Lasser**Author** A. Radenovic

Abstract Alzheimer's disease (AD) is characterized by amyloidosis of brain tissues. This phenomenon is studied with genetically-modified mouse models. We propose a method to quantify amyloidosis in whole 5x FAD mouse brains, a model of AD. We use optical projection tomography (OPT) and a random forest voxel classifier to segment and measure amyloid plaques. We validate our method in a preliminary cross-sectional study, where we measure 6136 ± 1637 , 8477 ± 3438 , and 17267 ± 4241 plaques (AVG $\pm$ SD) at 11, 17, and 31 weeks. Overall, this method can be used in the evaluation of new treatments against AD. © 2019 Optical Society of America under the terms of the OSA Open Access Publishing Agreement.

Supervised machine learning models for accurate prediction of micro pump displacement

Item Type Journal Article

Author F. Abid

Author M. Haddar

Author A. Elhami

Author M. Haddar

Abstract This study presents a supervised learning framework for predicting the maximum membrane displacement of a shape memory alloy (SMA) antagonistic micro pump subjected to material and geometric uncertainties. SMA micro pumps are indeed promising candidates for precise fluid control in microfluidics, but their nonlinear and hysteretic thermomechanical behavior makes parametric analyses and uncertainty evaluation using finite element analysis (FEA) methods particularly computationally expensive. To overcome this difficulty, a high-fidelity dataset comprising 500 design points was generated by three-dimensional simulation using a uniform randomized experimental design. Eight input parameters were investigated: five properties of the NiTi material (Young's modulus E , Poisson's ratio, hardening parameter h , yield strength R , and martensite end temperature M_f) and three geometric dimensions (thickness, membrane radius and spacer length). After preprocessing, five regression algorithms XGBoost, Gradient Boosting, LightGBM, Random Forest and Support Vector Regression were trained and optimized using RandomizedSearchCV and 5-fold cross-validation. Among these, XGBoost offered the best predictive performance, with,,, and across the entire test set. SHAP analysis showed that membrane thickness and radius are the most influential factors corroborating the physical consistency of the learned correlations. Learning curves and residual diagnostics confirmed the robustness of the XGBoost model. The proposed surrogate

model significantly reduces computation time relative to direct finite element methods based uncertainty quantification methods or reliability based design optimization while maintaining high predictive accuracy. These results demonstrate that machine learning based surrogate modeling constitutes an efficient and reliable complement to FEA for the design of SMA micro pumps in advanced microsystems. © The Author(s), under exclusive licence to Springer-Verlag GmbH Germany, part of Springer Nature 2026.

Supervised statistical learning prediction of soybean varieties and cultivation sites using rapid uplc-ms separation, method validation, and targeted metabolomic analysis of 31 phenolic compounds in the leaves

Item Type Journal Article

Author C.-S. Rha

Author E.K. Jang

Author Y.D. Hong

Author W.S. Park

Abstract Soybean (*Glycine max*; SB) leaf (SL) is an abundant non-conventional edible resource that possesses value-adding bioactive compounds. We predicted the attributes of SB based on the metabolomes of an SL using targeted metabolomics. The SB was planted in two cities, and SLs were regularly obtained from the SB plant. Nine flavonol glycosides were purified from SLs, and a validated simultaneous quantification method was used to establish rapid separation by ultrahigh-performance liquid chromatography-mass detection. Changes in 31 targeted compounds were monitored, and the compounds were discriminated by various supervised machine learning (ML) models. Isoflavones, quercetin derivatives, and flavonol derivatives were discriminators for cultivation days, varieties, and cultivation sites, respectively, using the combined criteria of supervised ML models. The neural model exhibited higher prediction power of the factors with high fitness and low misclassification rates while other models showed lower. We propose that a set of phytochemicals of SL is a useful predictor for discriminating characteristics of edible plants. © 2021 by the authors. Licensee MDPI, Basel, Switzerland.

Support vector machine learning-based cerebral blood flow quantification for arterial spin labeling MRI

Item Type Journal Article

Author Z. Wang

Abstract Purpose: To develop a multivariate machine learning classification-based cerebral blood flow (CBF) quantification method for arterial spin labeling (ASL) perfusion MRI. Methods: The label and control images of ASL MRI were separated using a machine-learning algorithm, the support vector machine (SVM). The perfusion-weighted image was subsequently extracted from the multivariate (all voxels) SVM classifier. Using the same pre-processing steps, the proposed method was compared with standard ASL CBF quantification method using synthetic data and in-vivo ASL images. Results: As compared with the conventional univariate approach, the proposed ASL CBF quantification method significantly improved spatial signal-to-noise-ratio (SNR) and image appearance of ASL CBF images. Conclusion: the multivariate machine learning-based classification is useful for ASL CBF quantification. Supporting Delay-Sensitive IoT Applications: A Machine Learning Approach

Item Type Conference Paper

Author A. Alnoman

Abstract In this paper, a supervised machine learning approach, namely, the decision tree is used to classify IoT applications based on their delay requirements. The decision-tree is trained and tested using simulated datasets to classify tasks into delay-sensitive and delay-insensitive based on the application features such as type and location. Delay-sensitive tasks are generally related to applications such as medical, manufacturing, and connected vehicles that require high service quality and short response time. Once delay-sensitive tasks are recognized, a prioritized scheduling mechanism is implemented to reduce the queueing delay at edge devices. Here, a two-class priority queueing system is used to model the scheduling mechanism at the edge device. Results show the effectiveness of machine learning in identifying delay-sensitive tasks that will experience shorter queueing delay at the edge device to enable high quality edge computing services. © 2020 IEEE.

Surface Electromyography Quantification Methods for Evaluating Muscle Activity in Dysphagia

Item Type Journal Article**Author** A.S. Noor**Author** H. Susanti**Author** M.I. Mandasari

Abstract Quantitative evaluation of stroke patients with the risk of swallowing disorder or dysphagia is required to support diagnosis and further rehabilitation planning. Fluoroscopy X-ray imaging usually is used for swallowing diagnosis, though it gives radiation exposure to patients. Therefore, quantification of muscle coordination patterns involved in swallowing based on surface electromyography (sEMG) was introduced. However, an adequate quantification of sEMG for dysphagia diagnosis still lacks standardization. In this work, potential sEMG signal features, namely the contraction duration (DUR), the time to peak of maximum contraction (TTP), and the total RMS power (TP), were further investigated to evaluate the swallowing processes in healthy subjects and post-stroke patients. The experimental scheme instructed the participant, i.e. 20 healthy subjects and 20 patients, to swallow 3 mL of water in normal swallowing mode and swallow saliva in dry swallowing mode. The proposed signal processing procedure helps to establish the feature extraction of the

three features mentioned earlier. For dysphagia assessment, with the support of our proposed signal processing procedure, DUR and TTP can be used together to improve diagnosis reliability. The characteristic of both features in healthy subjects was shorter than in post-stroke patients. Also, the TP feature is useful as additional information to evaluate the role of suprahyoid (SUP) and infrahyoid (INF) muscle groups which are very important in the swallowing process. These results are promising to provide a reliable set of features in the time domain for swallowing analysis. Notably, this can also be utilized as a feature for supporting the automatic classification of dysphagia diagnosis. © 2021 Penerbit Universiti Kebangsaan Malaysia. All rights reserved.

Abstract Bedrock property quantification is critical for predicting the hydrological response of watersheds to climate disturbances. Estimating bedrock hydraulic properties over watershed scales is inherently difficult, particularly in fracture-dominated regions. Our analysis tests the covariability of above- and belowground features on a watershed scale, by linking borehole geophysical data, near-surface geophysics, and remote sensing data. We use machine learning to quantify the relationships between bedrock geophysical/hydrological properties and geomorphological/vegetation indices and show that machine learning relationships can estimate most of their covariability. Although we can predict the electrical resistivity variation across the watershed, regions of lower variability in the input parameters are shown to provide better estimates, indicating a limitation of commonly applied geomorphological models. Our results emphasize that such an integrated approach can be used to derive detailed bedrock characteristics, allowing for identification of small-scale variations across an entire watershed that may be critical to assess the impact of disturbances on hydrological systems. Surrogate model uncertainty quantification for active learning reliability analysis

Item Type Journal Article

Author Y. PANG

Author S. ZHANG

Author P. LIANG

Author M. WANG

Author Z. GONG

Author X. SONG

Author Z. KAN

Abstract Surrogate models offer an efficient approach to tackle the computationally intensive evaluation of performance functions in reliability analysis. Nevertheless, the approximations inherent in surrogate models necessitate the consideration of surrogate model uncertainty in estimating failure probabilities. This paper proposes a new reliability analysis method in which the uncertainty from the Kriging surrogate model is quantified simultaneously. This method treats surrogate model uncertainty as an independent entity, characterizing the estimation error of failure probabilities. Building upon the probabilistic classification function, a failure probability uncertainty is proposed by integrating the difference between the traditional indicator function and the probabilistic classification function to quantify the impact of surrogate model uncertainty on failure probability estimation. Furthermore, the proposed uncertainty quantification method is applied to a newly designed reliability analysis approach termed SUQ-MCS, incorporating a proposed median approximation function for active learning. The proposed failure probability uncertainty serves as the stopping criterion of this framework. Through benchmarking, the effectiveness of the proposed uncertainty quantification method is validated. The empirical results present the competitive performance of the SUQ-MCS method relative to alternative approaches. © 2024

Sustainability Quantification and Valuation. I: Definitions, Metrics, and Valuations for Decision Making

Item Type Journal Article

Author D. Webb

Author B.M. Ayyub

Abstract The term sustainability has many definitions in varied contexts. The development of metrics requires an examination of these definitions and other related concepts in terms of their hierarchical and nesting relationships. An understanding of these relationships could offer a basis for introducing requirements and ultimately the adoption of working sustainability definitions for construction and manufacturing. A comparative examination of these definitions resulted in recommended general and construction-centric definitions. Sustainability definitions that meet a set of requirements offer appropriate bases for developing metrics and valuations methods. Classification of sustainability indicators follows naturally from its definition. A probabilistic quantification framework is proposed to produce a rational indicator set. Converting indicators to a probability of meeting or exceeding sustainability needs incorporates uncertainty explicitly and puts the quantification method into a well-established mathematical framework. Using simulation, full statistical and probabilistic analyses are available for use on the results in characterizing the uncertainty in the results. The concept of consequences resulting from sustainability impacts establishes economic valuation. Each indicator level has a corresponding loss or gain that can be monetized into an economic consequence. A simulation method is developed that allows for uncertainty characterization under a wide range of dependency assumptions. Indicator levels are simulated and the probability of

meeting or exceeding sustainability needs is calculated along with corresponding consequence values. Then, a final need probability and consequence value for the entire structure or manufacturing process is obtained. The complete result can be analyzed using any statistical or economic techniques desired including benefit-cost, trade-offs, directional cosines, or sensitivity analysis. © 2016 American Society of Civil Engineers.

Synthesis using fuzzy set theory and a Dempster-Shafer-based approach to compromise decision-making with multiple-attributes applied to risk control options selection

Item Type Journal Article

Author H.S. Sii

Author T. Ruxton

Author J. Wang

Abstract In decision-making there are always some parameters that are inaccurately known, meaning that the decision-making process must be based on subjective opinions. One of the useful aspects of fuzzy set theory is its ability to represent mathematically a class of decision problems called multiple objective decisions, with involvement of many vague (and thus fuzzy) goals and constraints. The objective of the fuzzy set decision methodology is to obtain an optimal decision in the sense that some set of goals is attained while observing (i.e., not violating) a simultaneous set of constraints. This paper presents a decision-making model as applied to multiple-attribute decision-making problems, which may be useful to decision-makers in many real-world problems. The proposed decision-making framework is a synthesis using an approach developed by Zadeh and Bellman in 1970 [1] and later extended by Yager, in 1977 [2], together with the Dempster-Shafer theory of evidence [3]. While dealing with a multiple-attribute decision-making problem the decision-maker may have to compromise with available alternatives, none of which may satisfy exactly his ultimate ideal best. The decision mechanism is constrained by the uncertainty and imprecision inherent in the determination of the relative importance of each attribute element and the classification of existing alternatives. The classification of alternatives is addressed through expert evaluation of the degree to which each attribute element is contained in each available alternative. The implementation of pairwise comparison and a ratio-scale quantification method by the decision-maker is performed to determine the relative importance of each attribute element. Then the 'belief and plausibility' that an alternative will satisfy the decision-maker's ideal 'best' are derived and combined to rank the available alternatives. Two examples in maritime safety engineering are presented to demonstrate the proposed framework.

Synthesizing Proton-Density Fat Fraction and R2* from 2-Point Dixon MRI with Generative Machine Learning

Item Type Conference Paper**Author** S. Anand**Author** K. Xu**Author** C. O'Dushlaine**Author** S. Mukherjee

Abstract Magnetic Resonance Imaging (MRI) is the gold standard for measuring fat and iron content non-invasively in the body via measures known as Proton Density Fat Fraction (PDFF) and R2*, respectively. However, conventional PDFF and R2* quantification methods operate on MR images voxel-wise and require at least three measurements to estimate three quantities: water, fat, and R2*. Alternatively, the two-point Dixon MRI protocol is widely used and fast because it acquires only two measurements; however, these cannot be used to estimate three quantities voxel-wise. Leveraging the fact that neighboring voxels have similar values, we propose using a generative machine learning approach to learn PDFF and R2* from Dixon MRI. We use paired Dixon-IDEAL data from UK Biobank in the liver and a Pix2Pix conditional GAN [1] to demonstrate the first large-scale R2* imputation from two-point Dixon MRIs. Using our proposed approach, we synthesize PDFF and R2* maps that show significantly greater correlation with ground-truth than conventional voxel-wise baselines. © 2025 IEEE.

Systematic Classification of Curvature and Feature Descriptor of 3D Shape and Its Application to “Complexity” Quantification Methods

Item Type Journal Article**Author** K. Matsuyama**Author** T. Shimizu**Author** T. Kato

Abstract Generative design is a system that automates part of the design process, but it cannot evaluate psychological issues related to shapes, such as “beauty” and “liking”. Designers therefore evaluate and choose the generated shapes based on their experience. Among the design features, “complexity” is considered to influence “aesthetic preference”. Although feature descriptors calculated from curvature can be used to quantify “complexity”, the selection guidelines for curvature and feature descriptors have not been adequately discussed. Therefore, this study aimed to conduct a systematic classification of curvature and a feature descriptor of 3D shapes and to apply the results to the “complexity” quantification. First, we surveyed the literature on curvature and feature descriptors and conducted a systematic classification. To quantify “complexity”, we used five curvatures (Gaussian curvature, mean curvature, Casorati curvature, shape index, and curvature index) and a feature descriptor (entropy of occurrence probability) obtained from the classification and compared them with the sensory evaluation values of “complexity”. The results showed that the determination coefficient between the quantified and sensory evaluation values of “complexity” was highest when the mean curvature was used. In addition, the Casorati curvature tended to show the highest signal-to-noise ratio (i.e., a high determination coefficient irrespective of the parameters set in the entropy calculation). These results will foster the development of generative design of 3D shapes using psychological evaluation. © 2023 by the authors.

Abstract Research into magnetic resonance imaging (MRI)-visible perivascular spaces (PVS) has recently increased, as results from studies in different diseases and populations are cementing their association with sleep, disease phenotypes, and overall health indicators. With the establishment of worldwide consortia and the availability of large databases, computational methods that allow to automatically process all this wealth of information are becoming increasingly relevant. Several computational approaches have been proposed to assess PVS from MRI, and efforts have been made to summarise and appraise the most widely applied ones. We systematically reviewed and meta-analysed all publications available up to September 2023 describing the development, improvement, or application of computational PVS quantification methods from MRI. We analysed 67 approaches and 60 applications of their implementation, from 112 publications. The two most widely applied were the use of a morphological filter to enhance PVS-like structures, with Frangi being the choice preferred by most, and the use of a U-Net configuration with or without residual connections. Older adults or population studies comprising adults from 18 years old onwards were, overall, more frequent than studies using clinical samples. PVS were mainly assessed from T2-weighted MRI acquired in 1.5T and/or 3T scanners, although combinations using it with T1-weighted and FLAIR images were also abundant. Common associations researched included age, sex, hypertension, diabetes, white matter hyperintensities, sleep and cognition, with occupation-related, ethnicity, and genetic/hereditary traits being also explored. Despite promising improvements to overcome barriers such as noise and differentiation from other confounds, a need

for joined efforts for a wider testing and increasing availability of the most promising methods is now paramount. © 2024 The Author(s)

Systematic Review of Quantitative Risk Quantification Methods in Construction Accidents

Item Type Journal Article

Author L. Kumi

Author J. Jeong

Author J. Jeong

Abstract Construction accidents pose significant risks to workers and the public, affecting industry productivity and reputation. While several reviews have discussed risk assessment methods, recent advancements in artificial intelligence (AI), big data analytics, and real-time decision support systems have created a need for an updated synthesis of the quantitative methodologies applied in construction safety. This study systematically reviews the literature from the past decade, following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. A thorough search identified studies utilizing statistical analysis, mathematical modeling, simulation, and artificial intelligence (AI). These methods were categorized and analyzed based on their effectiveness and limitations. Statistical approaches, such as correlation analysis, examined relationships between variables, while mathematical models, like factor analysis, quantified risk factors. Simulation methods, such as Monte Carlo simulations, explored risk dynamics and AI techniques, including machine learning, enhanced predictive modeling, and decision making in construction safety. This review highlighted the strengths of handling large datasets and improving accuracy, but also noted challenges like data quality and methodological limitations. Future research directions are suggested to address these gaps. This study contributes to construction safety management by offering an overview of best practices and opportunities for advancing quantitative risk assessment methodologies. © 2024 by the authors.

t-RAIN: Robust generalization under weather-aliasing label shift attacks

Item Type Conference Paper

Author A. Marathe

Author S. Prabhu

Abstract In the classical supervised learning settings, classifiers are fit with the assumption of balanced label distributions and produce remarkable results on the same. In the real world, however, these assumptions often bend and in turn adversely impact model performance. Identifying bad learners in skewed target distributions is even more challenging. Thus achieving model robustness under these "label shift" settings is an important task in autonomous perception. In this paper, we analyze the impact of label shift on the task of multi-weather classification for autonomous vehicles. We use this information as a prior to better assess pedestrian detection in adverse weather. We model the classification performance as an indicator of robustness under 4 label shift scenarios and study the behavior of multiple classes of models. We propose t-RAIN a similarity mapping technique for synthetic data augmentation using large scale generative models and evaluate the performance on DAWN dataset. This mapping boosts model test accuracy by 2.1, 4.4, 1.9, 2.7 % in no-shift, fog, snow, dust shifts respectively. We present state-of-the-art pedestrian detection results on real and synthetic weather domains with best performing 82.69 AP (snow) and 62.31 AP (fog) respectively. © 2023 IEEE.

Tackling the cybersecurity workforce gap with tailored cybersecurity study programs in Central and Eastern Europe

Item Type Conference Paper

Author M. Zivanovic

Author I. Lendák

Author R. Popovic

Abstract Digitalization of society brought improvement in many aspects of life but it also brought new cybersecurity challenges. The number of sophisticated, targeted cyber attacks is increasing, which requires constant improvements in Cybersecurity education. Despite this pressing need, the cybersecurity workforce gap is getting bigger. This paper presents a new approach for dynamic cybersecurity curriculum development that utilizes keyword extraction from various sources such as job ads, courses, and curricula with machine learning to quantify curriculum alignment with cybersecurity industry demands and address the workforce gap. The analysis illustrates curricula in the Central East Europe (CEE) region, maps cyber security job ads to curricula, and quantifies coverage of courses, industry, and reference framework topics based on keyword matching. The case study conducted with curricula from CEE illustrates coverage according to the ENISA's European Cybersecurity Skills Framework (ECSF) roles and optimization progress after adjustment application. The results demonstrate the importance of dynamic curriculum updates for academic institutions including cybersecurity workforce gap reduction and lack of real progress towards alignment with ECSF. © 2024 ACM.

Author T. Xu

Author B. Shen

Author W. Zhu

Abstract In online video systems, viewer demographic information (gender, age, etc.) is of huge commercial value for delivering targeted advertising and video recommendations, but generally not available directly. This paper targets inferring viewers' gender based on implicit watching history in the large-scale online video systems. To tackle the sparsity problem without filtering out any cold users or videos, we not only introduce video tags as features, but also use an efficient Chinese word segmentation method to extract hot key-words from video titles as features. Moreover, users' viewing behavior distribute lognormally, hence we apply a logarithmic transformation on the inference matrixes and further find key features via principal components analysis (PCA). We then solve the gender inference as a classification problem and define some modified evaluation metrics adapt to the imbalance classification problem. We compare a set of classifiers including Class prior, EM, SVM, Logistic regression, Partially supervised soft-label and belief-based mixture and find that Logistic regression is the best. The inference results show that our algorithms can obtain high FF1 values for all classes. The highest value of PPTV dataset can reach nearly 0.75. And inference based on key-words results in a 14.63% increase of F1 contrast to the ratings of MovieLens. © 2014 IEEE.

Target Distribution Agnostic Domain Adaptation for in-the-Wild Image Classification under Both Domain and Label Shifts

Item Type Conference Paper

Author A. Zheng

Author J.-N. Hwang

Author R. Hussein

Author F. Wallace

Author K. Magrane

Author L. Shiosaka

Abstract Although significant advancements have been made in Unsupervised Domain Adaptation (UDA), existing methods are typically validated on curated public datasets that do not adequately represent the complexities of real-world applications, such as imbalanced (long-tailed) label distributions and simultaneous domain and label shifts. To bridge this gap, we introduce the Target Distribution Agnostic Adaptation Network (TDAAN), a novel framework designed to facilitate robust adaptation from source to target domains under significant label shifts. Additionally, we present a new domain adaptation dataset,

MS-DA, which focuses on marine species and incorporates natural domain and label shifts, a feature sorely lacking in current domain adaptation research. Our experiments show that TDAAN not only significantly outperforms the baseline UDA method but also surpasses the performance of leading UDA methods on the MS-DA dataset. Remarkably, TDAAN maintains competitive performance on standard UDA benchmarks, proving its efficacy even in scenarios with minimal label shifts. These results position TDAAN as a superior method for UDA, particularly in real-world applications characterized by complex and diverse data distributions. Our code is available at <https://github.com/SEFSC/FATES-ATI-DomainAdaptationLabelShift>. © 2025 IEEE.

Techniques for evaluating the performance of landslide susceptibility models

Item Type Journal Article

Author P. Frattini

Author G. Crosta

Author A. Carrara

Abstract Evaluating the performance of landslide susceptibility models is needed to ensure their reliable application to risk management and land-use planning. When results from multiple models are available, a comparison of their performance is necessary to select the model which performs better. In this paper, different techniques to evaluate model performance are discussed and tested using shallow landslide/debris-flow susceptibility models recently presented in the literature (Carrara, A., Crosta, G.B., Frattini, P., 2008. Comparing models of debris-flow susceptibility in the alpine environment. *Geomorphology* 94 (3-4), 353-378). Moreover, an evaluation technique based on the minimization of costs that may arise from the adoption of the model as a land management regulatory tool, is presented. The results of the application show that simple statistics such as Accuracy, Threat score, Gilbert's skill score, Pierce's skill score, Heidke skill score, and Yule's Q are problematic as they need to split the classified objects into two classes (e.g., stable/unstable) by defining an a-priori value of cutoff susceptibility, which is often not trivial. ROC curves and Success-Rate curves are cutoff-independent and can be used to efficiently visualize and compare the performance of models, but do not explicitly include classification costs. In addition, Success-Rate curves, under certain conditions, can be misleading when applied to grid-cell models. Cost curves include costs and a-priori probabilities, and are suitable for landslide susceptibility model performance evaluation from a practical point of view. © 2009 Elsevier B.V. Author O. Engkvist

Abstract The estimation of uncertainties associated with predictions from quantitative structure–activity relationship (QSAR) models can accelerate the drug discovery process by identifying promising experiments and allowing an efficient allocation of resources. Several computational tools exist that estimate the predictive uncertainty in machine learning models. However, deviations from the i.i.d. setting have been shown to impair the performance of these uncertainty quantification methods. We use a real-world pharmaceutical dataset to address the pressing need for a comprehensive, large-scale evaluation of uncertainty quantification approaches in the context of realistic distribution shifts over time. We investigate the performance of several popular uncertainty estimation methods for classification models, including ensemble-based and Bayesian approaches. Furthermore, we use this real-world setting to systematically assess the distribution shifts in label and descriptor space and their impact on the capability of the uncertainty quantification methods. Our study reveals significant shifts over time in both label and descriptor space and a clear connection between the magnitude of the shift and the nature of the assay. Moreover, we show that pronounced distribution shifts impair the performance of popular uncertainty quantification methods used in QSAR models. This work highlights the challenges of identifying uncertainty quantification techniques that remain reliable under distribution shifts introduced by real-world data. © 2025 The Authors

Temporal Test-Time Adaptation with State-Space Models

Item Type Journal Article

Author M. Schirmer

Author D. Zhang

Author E. Nalisnick

Abstract Distribution shifts between training and test data are inevitable over the lifecycle of a deployed model, leading to performance decay. Adapting a model on test samples can help mitigate this drop in performance. However, most test-time adaptation methods have focused on synthetic corruption shifts, leaving a variety of distribution shifts underexplored. In this paper, we focus on distribution shifts that evolve gradually over time, which are common in the wild but challenging for existing methods, as we show. To address this, we propose STAD, a Bayesian filtering method that adapts a deployed model to temporal distribution shifts by learning the time-varying dynamics in the last set of hidden features. Without requiring labels, our model infers time-evolving class prototypes that act as a dynamic classification head. Through experiments on real-world temporal distribution shifts, we show that our method excels in handling small batch sizes and label shift. © 2025, Transactions on Machine Learning Research. Terminal Traffic Situation Prediction Model under the Influence of Weather Based on Deep Learning Approaches

Item Type Journal Article

Author L. Yuan

Author Y. Zeng

Author H. Chen

Author J. Jin

Abstract In order to quantify the degree of influence of weather on traffic situations in real time, this paper proposes a terminal traffic situation prediction model under the influence of weather (TSPM-W) based on deep learning approaches. First, a feature set for predicting traffic situations is constructed based on data such as weather, traffic demand, delay conditions, and flow control strategies. When constructing weather data, a terminal area weather quantification method (TAWQM) is proposed to quantify various weather feature values. When constructing the traffic situation label, fuzzy C-means clustering (FCM) is used to perform cluster analysis on the traffic situation, and the traffic situation is marked as bad, average, or good. Accordingly, the multi-source data is fused as the input vector, based on the combined prediction model of convolutional neural network (CNN) and gated recurrent unit (GRU), TSPM-W is constructed. Finally, based on the historical operation data of the Guangzhou Baiyun International Airport terminal area, the proposed data set is used to predict the traffic situation time series at intervals of 1 h, 3 h, and 6 h. The comparative experimental results show that the proposed time series prediction model has higher prediction accuracy than other existing prediction methods. The proposed dataset is able to more accurately predict the traffic situation in the terminal area. © 2022 by the authors.

Abstract When it comes the need to automatically recognize handwritten information, there may be a scenario in which the capture device (such as the camera of a mobile phone) retrieves several samples—a burst—of the same content. Unlike general classification scenarios, combining different inputs is not straightforward for state-of-the-art handwriting recognition approaches based on neural end-to-end formulations. Moreover, since not all images within the burst may depict enough quality for contributing in the overall recognition task, it is hence necessary to select the appropriate subset. In this work, we propose a pilot study which addresses this scenario in which there exists a burst of pictures of the same manuscript to transcribe. Within this context, we present a straightforward strategy to select a single candidate out of the elements of the burst which achieves the best possible transcription. Our hypothesis is that the best source image is that whose transcription most likely matches a Language Model (LM) estimated on the application domain—in this work implemented by means of n-grams. Our strategy, therefore, processes all the images of the burst and selects the transcription with the highest a priori probability according to the LM. Our experiments recreate this scenario in two typical benchmarks of Handwritten Text Recognition (HTR) and Handwritten Music Recognition (HMR), validating the goodness of our proposal and leaving room for promising future work. © 2022, Springer Nature Switzerland AG.

Abstract Class distribution plays an important role in learning deep classifiers. When the proportion of each class in the test set differs from the training set, the performance of classification nets usually degrades. Such a label distribution shift

problem is common in medical diagnosis since the prevalence of disease vary over location and time. In this paper, we propose the first method to tackle label shift for medical image classification, which effectively adapt the model learned from a single training label distribution to arbitrary unknown test label distribution. Our approach innovates distribution calibration to learn multiple representative classifiers, which are capable of handling different one-dominating-class distributions. When given a test image, the diverse classifiers are dynamically aggregated via the consistency-driven test-time adaptation, to deal with the unknown test label distribution. We validate our method on two important medical image classification tasks including liver fibrosis staging and COVID-19 severity prediction. Our experiments clearly show the decreased model performance under label shift. With our method, model performance significantly improves on all the test datasets with different label shifts for both medical image diagnosis tasks. Text mining analysis of teaching evaluation questionnaires for the selection of outstanding teaching faculty members

Item Type Journal Article

Author C.-W. Tseng

Author J.-J. Chou

Author Y.-C. Tsai

Abstract This paper was conducted in collaboration with the Office of Institutional Research at National Ilan University in Taiwan to analyze textual opinions found in teaching evaluation questionnaires and applied the analysis results to assisting the selection of outstanding teaching faculty members. The selection of outstanding teachers requires that selection committee members spend a large amount of time reviewing written data. Therefore, this paper develops a set of systems for the analysis of textual opinions in teaching evaluation questionnaires, providing reference materials for the selection committee. The teaching evaluation questionnaire is a form of educational data. This paper analyzes these data using educational data mining. In text mining, text sentiment analysis is a common textual data quantification method that can analyze the sentiment tendency of a text author. This paper uses a text sentiment analysis to quantify the students' textual opinions and to provide the selection committee with the sentiment tendency of students' comments on teaching faculty members. We analyze text sentiment separately for different classifiers by using the Chinese text sentiment analysis kit SnowNLP. We compare the efficacy of classifiers that do not take time series factors into consideration (naïve Bayes and fully connected neural network) to those that do [recurrent neural network (RNN), long short-term memory (LSTM) RNN, and attention RNN]. We found that classifiers that consider time series factors are more effective at analyzing text sentiment. Furthermore, adding LSTM cells and an attention mechanism to a traditional RNN classifier effectively improved its efficacy on long-sequence tasks. As a result, we chose the attention LSTM classifier-with a positive sentiment recognition rate of 97% and a negative sentiments recognition rate of 87%- A s our preferred text sentiment classifier. Finally, we set up an analytics server that will be modularized to facilitate its integration into the systems of different schools. © 2018 IEEE.

Abstract This paper is a preliminary attempt at gaining useful knowledge from student reports, but also at inspecting their predictive power on grades or course success rate. First a descriptive statistical analysis is done in order to get a basic understanding of patterns found in reports. Then a frequency word analysis and contrastive analysis are done in order to identify the most frequent words per class and those words that occur distinctively between different classes. Prior to the classification task, correlations between the length of the final report and the final grade, and between the scores obtained on each reported activity

individually and the final grade are inspected. Finally, four different classifiers are evaluated on the task of classifying texts based on the type. The same four classifiers are used to determine the predictive power that reports have on course final grades. Copyright © 2015 ACM.

Abstract In a number of applications involving text classification in recent years it has been pointed out that the final goal is not determining which class (or classes) individual unlabeled documents belong to, but determining the prevalence (or “relative frequency”) of each class in the unlabeled data. The latter task is known as text quantification (or prevalence estimation, or class prior estimation). The goal of this course was to introduce the audience to the problem of quantification, techniques that have been proposed for solving it, metrics used to evaluate them, applications in fields such as information retrieval, machine learning, and data mining, and to the open problems in the area. © Springer International Publishing Switzerland 2016.

Textural classification of mammographic parenchymal patterns with the SONNET selforganizing neural network

Item Type Journal Article

Author D. Howard

Author S.C. Roberts

Author C. Ryan

Author A. Brezulianu

Abstract In nationwide mammography screening, thousands of mammography examinations must be processed. Each consists of two standard views of each breast, and each mammogram must be visually examined by an experienced radiologist to assess it for any anomalies. The ability to detect an anomaly in mammographic texture is important to successful outcomes in mammography screening and, in this study, a large number of mammograms were digitized with a highly accurate scanner; and textural features were derived from the mammograms as input data to a SONNET selforganizing neural network. The paper discusses how SONNET was used to produce a taxonomic organization of the mammography archive in an unsupervised manner. This process is subject to certain choices of SONNET parameters, in these numerical experiments using the craniocaudal view, and typically produced $O(10)$, for example, 39 mammogram classes, by analysis of features from $O(10^3)$ mammogram images. The mammogram taxonomy captured typical subtleties to discriminate mammograms, and it is submitted that this may be exploited to aid the detection of mammographic anomalies, for example, by acting as a preprocessing stage to simplify the task for a computational detection scheme, or by ordering mammography examinations by mammogram taxonomic class prior to screening in order to encourage more successful visual examination during screening. The resulting taxonomy may help train screening radiologists and conceivably help to settle legal cases concerning a mammography screening examination because the taxonomy can reveal the frequency of mammographic patterns in a population. Author I. Santana

Author M. Castelo-Branco

Abstract Alzheimer's disease is the most common form of dementia worldwide, accounting for 60–70% of diagnosed cases. According to the current understanding of molecular pathogenesis, the main hallmarks of this disease are the abnormal accumulation of amyloid plaques and neurofibrillary tangles. Therefore, biomarkers reflecting these underlying biological mechanisms are recognized as valid tools for an early diagnosis of Alzheimer's disease. Inflammatory mechanisms, such as microglial activation, are known to be involved in Alzheimer's disease onset and progression. This activated state of the microglia is associated with increased expression of the translocator protein 18 kDa. On that account, PET tracers capable of measuring this signature, such as (R)-[11C]PK11195, might be instrumental in assessing the state and evolution of Alzheimer's disease. This study aims to investigate the potential of Gray Level Co-occurrence Matrix-based textural parameters as an alternative to conventional quantification using kinetic models in (R)-[11C] PK11195 PET images. To achieve this goal, kinetic and textural parameters were computed on (R)-[11C]PK11195 PET images of 19 patients with an early diagnosis of Alzheimer's disease and 21 healthy controls and submitted separately to classification using a linear support vector machine. The classifier built using the textural parameters showed no inferior performance compared to the classical kinetic approach, yielding a slightly larger classification accuracy (accuracy of 0.7000, sensitivity of 0.6957, specificity of 0.7059 and balanced accuracy of 0.6967). In conclusion, our results support the notion that textural parameters may be an alternative to conventional quantification using kinetic models in (R)-[11C]PK11195 PET images. The proposed quantification method makes it possible to use simpler scanning procedures, which increase patient comfort and convenience. We further speculate that textural parameters may also provide an alternative to kinetic analysis in (R)-[11C]PK11195 PET neuroimaging studies involving other neurodegenerative disorders. Finally, we recognize that the potential role of this tracer is not in diagnosis but rather in the assessment and progression of the diffuse and dynamic distribution of inflammatory cell density in this disorder as a promising therapeutic target. © The Author(s) 2023. Texture analysis for automated classification of geologic structures

Item Type Conference Paper

Author V. Shankar

Author J.J. Rodriguez

Author M.E. Gettings

Abstract Texture present in aeromagnetic anomaly images offers an abundance of useful geological information for discriminating between rock types, but current analysis of such images still relies on tedious, human interpretation. This study is believed to be the first effort to quantitatively assess the performance of texture-based digital image analysis for this geophysical exploration application. We computed several texture measures and determined the best subset using automated feature selection techniques. Pattern classification experiments measured the ability of various texture measures to automatically predict rock types. The classification

accuracy was significantly better than a priori probability and prior weights-of-evidence results. The accuracy rates and choice of texture measures that minimize the error rate are reported. © 2006 IEEE.

The analysis of discrete data by machine learning : - Taking momentum in tennis match as an example

Item Type Conference Paper

Author J. Feng

Author Z. Wang

Author J. Xu

Abstract In tennis matches, comebacks often occur, and the existence of rules such as breaking and holding serve increases the probability of such situations. When a comeback happens, there is often a shift or fluctuation in "momentum." However, tennis data is mostly discrete, making it difficult to quantify the fluctuations in "momentum." We will use the random forest algorithm model in machine learning to quantify these fluctuations and assess the main influencing factors of the fluctuations through the method of feature importance index. Subsequently, we will summarize the factors affecting the "momentum" of different athletes and

analyze the data through the comprehensive scoring index method, observing the correlation between "momentum" factors. After that, we will conduct a sensitivity analysis of the model and find that the model remains stable even when adjusting 0-5 factors. Finally, we will provide relevant suggestions based on the influencing factors of "momentum" fluctuations summarized for different athletes. © 2024 IEEE.

Abstract MRI imaging is less risky to humans than CT scans, but is more difficult to extract information from due to the ambiguous gray levels. The objective of the paper is to describe a novel technique that has been developed to automate the measurement of the abdominal subcutaneous adipose tissue (SAT) and visceral adipose tissue (VAT) from MRI images for obese patients before and after fasting. Ground truth has been established with clinicians' inspection. Three hundred thirty images have been utilized in this study where deep learning and Convolutional Neural Networks have been employed to quantify SAT and VAT. This work would minimize the time doctors spend analyzing MRI images. © 2019 IEEE.

The association between estimated glucose disposal rate and self-reported diabetic retinopathy: evidence from two independent cohorts and machine learning

Item Type Journal Article

Author C. Yuan

Author Y. Hao

Author J. Wang

Author C. Wang

Author Z. Jiang

Abstract Background – Insulin resistance plays a key role in the pathogenesis of diabetic retinopathy (DR). Although established insulin resistance markers have been shown to predict a variety of complications, the association between the estimated glucose disposal rate (eGDR) and prevalence of DR remains incompletely characterized. This study aims to examine the relationship between eGDR and DR prevalence. Methods – This cross-sectional study analyzed complete participant data (N = 1, 536) from the 2007–2018 National Health and Nutrition Examination Survey (NHANES) for all relevant information. The relationship between the insulin resistance index and self-reported DR prevalence was evaluated by using multivariate logistic regression and a restricted cubic spline (RCS) model. Subgroup analysis was conducted to assess heterogeneity across groups, and two sensitivity analyses were performed to assess the robustness of the results. In machine learning, the Boruta algorithm is applied for feature selection. The selected features are subsequently utilized by XGBoost and random forest models for DR prevalence estimation. Use the Shapley additive explanations (SHAP) value to explain the independent contribution of eGDR. In the clinical cohort, we recruited patients who visited the Second Affiliated Hospital of Anhui Medical University from September 1, 2025, to December 30, 2025. A total of 297 participants who met the inclusion criteria were finally enrolled. Multivariable logistic regression and RCS curves were used to validate the findings from the NHANES analysis. Results – In the fully adjusted model, eGDR and self-reported DR prevalence show a significant negative linear correlation (OR = 0.79, 95% CI: 0.67–0.93, P = 0.0049). Subgroup and sensitivity analyses confirm the stability of this negative association. The Boruta algorithm identifies eGDR as a robust and important feature. Both the XGBoost (AUC = 0.773) and random forest (AUC = 0.764) models show moderate predictive performance, and eGDR has high variable importance. SHAP analysis indicates that eGDR, together with body mass index and income poverty, is a key determinant of self-reported DR prevalence. The results of the clinical cohort are like NHANES. Conclusion – This cross-sectional study suggested that lower eGDR is associated with a higher prevalence of self-reported DR. Accordingly, eGDR may serve as a potential marker for risk stratification rather than a causal or preventive factor. Prospective longitudinal research is necessary to confirm these findings and to explore whether a causal relationship exists. Copyright © 2026 Yuan, Hao, Wang, Wang and Jiang.

The changing patterns and correlates of population-level polysubstance use in Australian youth: a multi-group latent class analysis of nationally representative samples spanning 12 years

Item Type Journal Article

Author G. Chan

Author J. Connor

Author W. Hall

Author J. Leung

Abstract Aims: To (1) identify population-level classes of polysubstance use among young Australians between 2004 and 2016, (2) test if these classes changed over the same period, in terms of class prevalence and probabilities of substance use within each class, and (3) identify demographic and health-related correlates of polysubstance use. Design: Repeated cross-sectional nationally representative household surveys. Setting: All Australian states/territories. Participants: Young adult samples (aged 18–30 years; 58% females) from the National Drug Strategy Household Surveys (n = 20 350). Measurements: Outcomes were the extent of past-year use of 10 licit (e.g. alcohol), and illicit substances (e.g. cannabis) were used to derive polysubstance use classes. The correlates were gender, age, psychological distress, general health, language background, personal income, education level, remoteness of residence and socio-economic index for area of residence. Findings: Three polysubstance use classes were consistently identified between 2004 and 2016 (SSABIC: 188349): minimal users (MU, ~60%), mainly tobacco, alcohol and cannabis users (TAC, ~30%) and extended range polysubstance users (POLY, ~10%). There were substantial changes in use of different substances within each class over the study period. For example, smoking decreased in all classes ($P < 0.05$), while harmful alcohol use only decreased in the first two classes ($P < 0.05$). Factors associated with TAC and POLY were similar over the study period. These included: being male and having an English-speaking background, a high level of psychological distress, suboptimal health and high personal income. Living in an affluent area was associated with reduced likelihood of being TAC, but an increased likelihood of being POLY. Conclusion: At the population-level among young Australians between 2004 and 2016, six in 10 did not engage in polysubstance use; four in 10 used a limited range of substances (mainly alcohol, tobacco and cannabis) and one in 10 used an extended range of substances. Over time, the types of substance within the extended polysubstance use class changed substantially. © 2019 Society for the Study of Addiction

The cost-effectiveness of reclassification sampling for prevalence estimation

Item Type Journal Article

Author A. Bekmetjev

Author D. VanBruggen

Author B. McLellan

Author B. DeWinkle

Author E. Lunderberg

Author N. Tintle

Abstract Background: Typically, a two-phase (double) sampling strategy is employed when classifications are subject to error and there is a gold standard (perfect) classifier available. Two-phase sampling involves classifying the entire sample with an imperfect classifier, and a subset of the sample with the gold-standard. Methodology/Principal Findings: In this paper we consider an alternative strategy termed reclassification sampling, which involves classifying individuals using the imperfect classifier more than one time. Estimates of sensitivity, specificity and prevalence are provided for reclassification sampling, when either one or two binary classifications of each individual using the imperfect classifier are available. Robustness of estimates and design decisions to model assumptions are considered. Software is provided to compute estimates and provide advice on the optimal sampling strategy. Conclusions/Significance: Reclassification sampling is shown to be cost-effective (lower standard error of estimates for the same cost) for estimating prevalence as compared to two-phase sampling in many practical situations. © 2012 Bekmetjev et al.

The course of infection of *Encephalitozoon cuniculi* genotype I in mice possess combination of features reported in genotypes II and III

Item Type Journal Article**Author** B. Sak**Author** K. Brdíčková**Author** N. Holubová**Author** D. Květoňová**Author** L. Hlásková**Author** M. Kváč

Abstract Out of three genotypes of *Encephalitozoon cuniculi* (I–III) available for experimental studies, *E. cuniculi* genotype I remains the less characterized. This study describes for the first time individual phases of microsporidiosis caused by *E. cuniculi* genotype I and efficacy of albendazole treatment in immunocompetent BALB/c and C57Bl/6 mice and immunodeficient SCID, CD4^{−/−} and CD8^{−/−} mice using molecular detection and quantification methods. We demonstrate asymptomatic infection despite an intense dissemination of microsporidia into most organs within the first weeks post infection, followed by a chronic infection characterized by significant microsporidia persistence in immunocompetent, CD4^{−/−} and CD8^{−/−} mice and a lethal outcome for SCID mice. Albendazole application led to loss *E. cuniculi* genotype I infection in immunocompetent mouse strains, decreased spore burden by half in CD4^{−/−} and CD8^{−/−} mice, and prolongation of survival of SCID mice. These results showed *Encephalitozoon cuniculi* genotype I infection extend and albendazole sensitivity was comparable to *E. cuniculi* genotype II, but the infection onset speed

and mortality rate was similar to *E. cuniculi* genotype III. These imply that differences in the course of infection and the response to treatment depend not only on immunological status of the host, but also on the genotype causing the infection. © 2021 Elsevier Inc.

The double-edged effects of regional environmental governance: evidence from policy tools of belt and road initiative

Item Type Journal Article

Author H. Hu

Abstract Regional environmental governance plays a pivotal role in global climate cooperation; however, the effectiveness of specific policy tools, especially their interactions, remains underexplored. The Belt and Road Initiative (BRI), with over 140 participating countries, provides a unique empirical context to assess how regional environmental governance affects carbon dynamics. Here, construct a novel dataset of 282 BRI agreements (2014–2024) and apply a multi-period difference-in-differences model, complemented by machine learning to quantify causal effects and identify synergistic interactions. Results indicate a dual impact: while BRI environmental governance significantly reduces carbon intensity, it simultaneously increases overall carbon footprints due to infrastructure expansion and trade growth. Further, there is substantial heterogeneity in the effectiveness of individual instruments, which demonstrates that certain policy combinations amplify mitigation in developed regions but exacerbate emissions in developing economies. These findings highlight the urgent need to tailor regional governance frameworks to local contexts and long-term sustainability goals. Our research makes three contributions: (1) it introduces a text-based empirical strategy to identify and classify environmental policy tools embedded in international agreements; (2) it provides the first integrated causal and machine-learning-based assessment of policy heterogeneity and synergy under the BRI framework; and (3) it advances methodological innovation in evaluating transnational environmental governance using multi-period panel data with staggered treatment. © The Author(s) 2025.

The effect of class imbalance on case selection for case-based classifiers, with emphasis on computer-aided diagnosis systems

Item Type Conference Paper

Author J.M. Malof

Author M.A. Mazurowski

Author G.D. Tourassi

Abstract In this paper the effect of class imbalance in the case base of a case-based classifier is investigated as it pertains to case base reduction and the resulting classifier performance. A k-nearest neighbor algorithm is used as a classifier and the Random Mutation Hill Climbing (RMHC) algorithm is used for case base reduction. The effects at various levels of positive class prevalence are tested in a binary classification problem. The results indicate that class imbalance is detrimental to both case base reduction and classifier performance. Selection with RMHC generally improves the classification performance regardless of the case base prevalence. ©2009 IEEE.

The Effects of Artificial Diets on the Expression of Molecular Marker Genes Related to Honey Bee Health

Item Type Journal Article**Author** O. Frunze**Author** H. Kim**Author** J.-H. Lee**Author** H.-W. Kwon

Abstract Honey bees are commonly used to study metabolic processes, yet the molecular mechanisms underlying nutrient transformation, particularly proteins and their effects on development, health, and diseases, still evoke varying opinions among researchers. To address this gap, we investigated the digestibility and transformation of water-soluble proteins from four artificial diets in long-lived honey bee populations (*Apis mellifera ligustica*), alongside their impact on metabolism and DWV relative expression ratio, using transcriptomic and protein quantification methods. Diet 2, characterized by its high protein content and digestibility, was selected for further analysis from the other studied diets. Subsequently, machine learning was employed to identify six diet-related molecular markers: SOD1, Trxr1, defensin2, JHAMT, TOR1, and vg. The expression levels of these markers were found to resemble those of honey bees who were fed with Diet 2 and bee bread, renowned as the best natural food. Notably, honey bees exhibiting chalkbrood symptoms (Control-N) responded differently to the diet, underscoring the unique nutritional effects on health-deficient bees. Additionally, we proposed a molecular model to elucidate the transition of long-lived honey bees from diapause to development, induced by nutrition. These findings carry implications for nutritional research and beekeeping, underscoring the vital role of honey bees in agriculture. © 2024 by the authors.

The epidemiology of chronic venous insufficiency and varicose veins

Item Type Journal Article

Author J.L. Beebe-Dimmer

Author J.R. Pfeifer

Author J.S. Engle

Author D. Schottenfeld

Abstract Chronic venous disease is a common condition presenting to physicians in Western Europe and the United States. This article provides a comprehensive review of the published literature in the English language, from 1942 to the present, and focuses on the prevalence of chronic venous insufficiency and varicose veins, as well as the involved risk factors. Prevalence estimates vary widely by geographic location, with the highest reported rates in Western countries. Reports of prevalence of chronic venous insufficiency vary from < 1% to 40% in females and from < 1% to 17% in males. Prevalence estimates for varicose veins are higher, <1% to 73% in females and 2% to 56% in males. The reported ranges in prevalence estimations presumably reflect differences in the population distribution of risk factors, accuracy in application of diagnostic criteria, and the quality and availability of medical diagnostic and treatment resources. Established risk factors include older age, female gender, pregnancy, family history of venous disease, obesity, and occupations associated with orthostasis. Yet, there are several factors that are not well documented, such as diet, physical activity and exogenous hormone use, which may be important in the development of chronic venous disease and its clinical manifestations. © 2004 Elsevier Inc. The Gene Taxonomic Prevalence (GeTPrev) Pipeline for Scalable Gene Prevalence Estimation Across Bacterial Taxa

Item Type Journal Article

Author W. Wu

Author A.M. Dickey

Author J.L. Vipham

Author T.M. Arthur

Author J.W. Schmidt

Abstract The National Center for Biotechnology Information (NCBI) stores over 1 million bacterial genome sequences, with no tools capable of estimating the prevalence of specific nucleotide sequences within or across taxa. To address this gap, we developed the Gene Taxonomic Prevalence (GeTPrev) pipeline. GeTPrev estimates the presence of user-specified genes in bacterial genome collections across taxa. Implemented in Bash, GeTPrev integrates BLAST-based sequence alignment with

two operational modes tailored to different analytical needs. The default mode performs a one-pass search against curated complete genome databases formatted for BLAST. A “Heavy” mode expands the search to include both complete and draft genomes for a broader representation of genomic diversity. GeTPrev is managed through a Conda environment and designed for compatibility with high-performance computing (HPC) systems, enabling efficient batch analysis of large genome datasets. GeTPrev supports the construction of user-defined gene taxonomic targets. However, prebuilt complete genome databases of seven Enterobacteriaceae genera are included with the pipeline to support rapid analysis. GeTPrev functionality and flexibility were demonstrated by nine example applications. GeTPrev offers a practical solution for gene-centric analysis in microbial genomics, molecular epidemiology, and food safety surveillance. © 2026

The Groups and Nilpotent Lie Rings of Order p^8 with Maximal Class

Item Type Journal Article

Author S. Lee

Author M. Vaughan-Lee

Abstract We classify and count the nilpotent Lie rings of order p^8 with maximal class for (Formula presented.). This also provides a classification of the groups of order p^8 with maximal class for (Formula presented.) via the Lazard correspondence. We also record the number of nilpotent Lie rings/groups of order p^n with maximal class for (Formula presented.) from currently known data and discuss its asymptotic behavior as n grows and its potential connection to Higman's PORC conjecture. © 2022 Taylor & Francis Group, LLC.

The Hitchhiker's Guide to Prior-Shift Adaptation

Item Type Conference Paper

Author T. Sipka

Author M. Sulc

Author J. Matas

Abstract In many computer vision classification tasks, class priors at test time often differ from priors on the training set. In the case of such prior shift, classifiers must be adapted correspondingly to maintain close to optimal performance. This paper analyzes methods for adaptation of probabilistic classifiers to new priors and for estimating new priors on an unlabeled test set. We propose a novel method to address a known issue of prior estimation methods based on confusion matrices, where inconsistent estimates of decision probabilities and confusion matrices lead to negative values in the estimated priors. Experiments on fine-grained image classification datasets provide insight into the best practice of prior shift estimation and classifier adaptation, and show that the proposed method achieves state-of-the-art results in prior adaptation. Applying the best practice to two tasks with naturally imbalanced priors, learning from web-crawled images and plant species classification, increased the recognition accuracy by 1.1% and 3.4% respectively. © 2022 IEEE.

The impact of the #MeToo movement on language at court A text-based causal inference approach

Item Type Journal Article

Author H. Langen

Abstract This study assesses the effect of the #MeToo movement on the language used in judicial opinions on sexual violence related cases from 51 U.S. state and federal appellate courts. The study introduces various indicators to quantify the extent to which actors in courtrooms employ language that implicitly shifts responsibility away from the perpetrator and onto the victim. One indicator measures how frequently the victim is mentioned as the grammatical subject, as research in the field of psychology suggests that victims are assigned more blame the more often they are referred to as the grammatical subject. The other two indices designed to gauge the level of victim-blaming capture the sentiment of and the context in sentences referencing the perpetrator. Additionally, judicial opinions are transformed into bag-of-words and tf-idf vectors to facilitate the examination of the evolution of language over time. The causal effect of the #MeToo movement is estimated by means of a Difference-in-Differences approach comparing the development of the language in opinions on sexual offenses and other crimes against persons as well as a Panel Event Study approach. The results do not clearly identify a #MeToo-movement-induced change in the language in court but suggest that the movement may have accelerated the evolution of court language slightly, causing the effect to materialize with a significant time lag. Additionally, the study considers potential effect heterogeneity with respect to the judge's gender and political affiliation. The study combines causal inference with text quantification methods that are commonly used for classification as well as with indicators that rely on sentiment analysis, word embedding models and grammatical tagging. © 2024 Henrika Langen. The implementation of intelligent systems in automating vehicle detection on the road

Item Type Journal Article

Author D.D. Budiarjo

Author A. Hendrawan

Author P.T. Pungkasanti

Abstract Indonesia is a country with a high population, especially in big cities. The road always crowded with various types of vehicles. Sometimes the growth of vehicles is not matched by road construction. During peak hours, too many vehicles can cause traffic jams on the road. The road is needed to be widened to accommodate the number of vehicles that pass each day. In order for road widening to be precise at locations that frequently occur in traffic jams, data on the number and classification of vehicles passing is required. Therefore, a system that can calculate and recognize the type of vehicle that passes is needed. The development of various studies on artificial intelligence especially about object detection can classify and calculate the type of vehicle. In this study, the authors used the YOLO object detection system using a convolution neural network (CNN) method to classify and count vehicles that pass automatically. The author uses a dataset of 600 images with 4 classes which are car, truck, bus, and motorbikes that pass through the road. The results showed that the YOLO object detection system can recognize objects consistently with accuracy more than 80% on CCTV video that installed on the road. © 2021, Institute of Advanced Engineering and Science. The importance of the test set size in quantification assessment

Item Type Conference Paper**Author** A. Maletzke**Author** W. Hassan**Author** D. dos Reis**Author** G. Batista**Editor** Bessiere C.

Abstract Quantification is a task similar to classification in the sense that it learns from a labeled training set. However, quantification is not interested in predicting the class of each observation, but rather measure the class distribution in the test set. The community has developed performance measures and experimental setups tailored to quantification tasks. Nonetheless, we argue that a critical variable, the size of the test sets, remains ignored. Such disregard has three main detrimental effects. First, it implicitly assumes that quantifiers will perform equally well for different test set sizes. Second, it increases the risk of cherry-picking by selecting a test set size for which a particular proposal performs best. Finally, it disregards the importance of designing methods that are suitable for different test set sizes. We discuss these issues with the support of one of the broadest experimental evaluations ever performed, with three main outcomes. (i) We empirically demonstrate the importance of the test set size to assess quantifiers. (ii) We show that current quantifiers generally have a mediocre performance on the smallest test sets. (iii) We propose a meta-learning scheme to select the best quantifier based on the test size that can outperform the best single quantification method. © 2020 Inst. Sci. inf., Univ. The incidence of different removable partial denture cases related to age, gender and arch in a distinct population in Iraq

Item Type Journal Article

Author M.M. Refaat

Author N.A. Al-Shareeda

Author A.M. Hussain

Abstract Background: The classification of partially dentate cases allow identification the relation of teeth to edentulous ridges combinations, it investigate the partially edentulism pattern. Kennedy's classification system permit immediate visualization and recognition of different edentulous spaces in the dental arch. Aims of the study: Assessment the prevalence of the partially edentulous patients in Basrah city/south of Iraq and determines the correlation with age, arches and gender. Materials and Methods: A cross-sectional study is applied for 1000 partially edentulous male and female patients above 20 years age. Data collection based on face to face interview and clinical examination. Results: According to the collected data, Kennedy's cases of Class III were the most popular for both genders. The least was Class IV being less common pattern, its prevalence for males more than females. Maxilla is more than mandible in partially edentulism cases. Conclusion: Kennedy most common

classification for both maxilla and mandible dentalarches was Class III. The various classes prevalence not affected by gender, while patient age had a significant effect.

The influence of building energy performance prediction accuracy on retrofit rates

Item Type Journal Article

Author C. Wiethe

Author S. Wenninger

Abstract The residential building sector bears enormous CO2 emission reduction potential. However, uncertainty connected to financial savings of retrofits, stemming largely from inaccurate building energy performance predictions, forms a significant investment barrier. So far, literature does not sufficiently cover the relationship between prediction accuracy and retrofit rates. Thus, this paper aims to provide guidance for policymakers by setting up an agent-based building stock model to derive this relationship for the German residential building sector assuming rational decision-making. Results indicate that higher prediction accuracies positively affect the retrofit rate. Using data-driven prediction methods established in research

significantly increases the retrofit rate by over 70%, from around 0.98% – 1.68% compared to the legally prescribed engineering method. This equals CO2 emission reductions of almost 45 Mt by 2050 for Germany, leading to a surplus in consumer rent of 310.19 mn €, while investments in retrofits increase by about 1.195 bn €. The government benefits from tax payments and saves opportunity costs. The findings allow to estimate the effect of revising current legislation on building energy performance predictions and thereby clearly guide policymakers. © 2023 Elsevier Ltd

The influence of SAR image quantization method on detection precision

Item Type Conference Paper

Author B. Sun

Author Z. Zuo

Author P. Wang

Abstract In this paper, we combine deep learning with radar image processing to explore the influence of different quantization methods on the final detection performance of the radar image subjected to strong points after different quantification methods. Considering problems caused by the characteristics of SAR image data, the LeNet network model in deep learning was used to train and verify the quantified radar images respectively. The impact of different quantization methods on SAR image classification and detection was analyzed. The most friendly way to quantify the actual radar images was explored. Radar image target detection based on depth learning provides the basis for exploration. © 2018 IEEE.

Abstract To promote climate adaptation and mitigation strategies, it is crucial to understand the perspectives and knowledge gaps of stakeholders involved in functions affected by or addressing land use and climate changes. A large number of stakeholders across 21 European islands were consulted regarding their views on climate change and land use change issues affecting ecosystem services on their island. Climate change characteristics perceptions included variables such as temperature, precipitation, humidity, extremes, and wind. Land use change characteristics perceptions included deforestation, coastal degradation, habitat protection, renewable energy facilities, wetlands and other variables. Other environmental and societal problem perceptions such as invasive species, water or energy scarcity, problems in infrastructures or austerity were also included. Climate and land use change impact perceptions were analysed with machine learning to quantify their importance on the perception outcome. For example if a stakeholder perceives that pollution, coastal degradation, deforestation, precipitation decrease, and increase of humidity are occurring on the island, and austerity is the biggest problem how likely is that the impact of climate change or land use change will be quantified by the stakeholder as negative, unclear, neutral, or positive? The predominant climatic change characteristic is related with temperature, and the predominant land use change characteristic with deforestation.

Water-related problems are top priorities for stakeholders. Energy-related problems, such as energy deficiency but also wind and solar energy facilities problems, rank high as combined climate change and land use change risks. Stakeholders generally perceive climate change impacts on ecosystem services as negative, with natural habitat destruction and biodiversity loss identified as the top variables. Land use change impacts are also negative but also more complex to explain, with a higher number of explanatory variables associated with the impact outcome. Stakeholders have common perceptions regarding climate change and land use change impacts on the benefits of biodiversity despite the geographic disparity. Stakeholders differentiate between factors related to climate change impacts and land use change impacts. Water, energy, and renewable energy related issues pose serious concerns to island stakeholders and management measures are needed to address them. © 2025 The Authors

The long road to calibrated prediction uncertainty in computational chemistry

Item Type Journal Article**Author** P. Pernot

Abstract Uncertainty quantification (UQ) in computational chemistry (CC) is still in its infancy. Very few CC methods are designed to provide a confidence level on their predictions, and most users still rely improperly on the mean absolute error as an accuracy metric. The development of reliable UQ methods is essential, notably for CC to be used confidently in industrial processes. A review of the CC-UQ literature shows that there is no common standard procedure to report or validate prediction uncertainty. I consider here analysis tools using concepts (calibration and sharpness) developed in meteorology and machine learning for the validation of probabilistic forecasters. These tools are adapted to CC-UQ and applied to datasets of prediction uncertainties provided by composite methods, Bayesian ensembles methods, and machine learning and a posteriori statistical methods. © 2022 Author(s).

The Magnitude and Impact of Food Allergens and the Potential of AI-Based Non-Destructive Testing Methods in Their Detection and Quantification

Item Type Journal Article

Author A.A. Adedeji

Author P.V. Priyesh

Author A.A. Odugbemi

Abstract Reaction to food allergens is on the increase and so is the attending cost on consumers, the food industry, and society at large. According to FDA, the “big-eight” allergens found in foods include wheat (gluten), peanuts, egg, shellfish, milk, tree nuts, fish, and soybeans. Sesame was added to the list in 2023, making the target allergen list nine instead of eight. These allergenic foods are major ingredients in many food products that can cause severe reactions in those allergic to them if found at a dose that can elicit a reaction. Defining the level of contamination that can elicit sensitivity is a work in progress. The first step in preventing an allergic reaction is reliable detection, then an effective quantification method. These are critical steps in keeping contaminated foods out of the supply chain of foods with allergen-free labels. The conventional methods of chemical assay, DNA-PCR, and enzyme protocols like enzyme-linked immunosorbent assay are effective in allergen detection but slow in providing a response. Most of these methods are incapable of quantifying the level of allergen contamination. There are emerging non-destructive methods that combine the power of sensors and machine learning to provide reliable detection and quantification. This review paper highlights some of the critical information on the types of prevalent food allergens, the mechanism of an allergic reaction in humans, the measure of allergenic sensitivity and eliciting doses, and the conventional and emerging AI-based methods of detection and quantification—the merits and downsides of each type. © 2024 by the authors.

The Mechanism and Empirical Study on the Empowerment of Chinese Cultural Product Exports through the Digital Economy under the RCEP Institutional Framework

Item Type Conference Paper

Author H. Zhou

Author Q. Wu

Abstract Based on the panel data of China and RCEP partner countries from 2007 to 2022, this paper constructs a digital economy measurement system by employing principal component analysis, a core dimensionality reduction algorithm in machine learning, to quantify the level of digital economy development. The extended trade gravity model is used to analyse the impact of digital economy development on China's cultural product exports. The study leverages core computer technologies, including big data analytics for processing trade and consumption data, and incorporates discussions on the roles of AI-driven content adaptation and blockchain-based transaction systems. The study finds that: the development of the digital economy in RCEP partner countries has a significant positive effect on China's cultural product exports. This underscores the critical role of underlying digital infrastructure and data-driven decision-making. The heterogeneity test shows that the improvement of digital economy level in developing countries has a more prominent role in promoting China's cultural product exports, suggesting that algorithm and platform design should consider regional disparities. Accordingly, it puts forward policy suggestions such as strengthening intelligent digital infrastructure and AI-powered content adaptation tools, establishing blockchain-based copyright and transaction mechanisms, focusing on digital cultural exports to RCEP developing country markets, participating in formulating international technical standards for digital cultural assets, and building a national-level cloud-native digital cultural export platform, so as to promote the high-quality development of China's cultural product export trade and provide insights for the development of computational economic models. © 2025 Copyright held by the owner/author(s).

Abstract River flows change on timescales ranging from minutes to millennia. These vibrations in flow are tuned by diverse factors globally, for example, by dams suppressing multi-day variability or vegetation attenuating flood peaks in some

ecosystems. The relative importance of the physical, biological, and human factors influencing flow is an active area of research, as is the related question of finding a common language for describing overall flow regime. Here, we addressed both topics using a daily river discharge data set for over 3,000 stations across the globe from 1988 to 2016. We first studied similarities between common flow regime quantification methods, including traditional flow metrics, wavelets, and Fourier analysis. Across all these methods, the flow data showed low-dimensional structure (i.e., simple and consistent patterns), suggesting that fundamental mechanisms are constraining flow regime. One such pattern was that day-to-day variability was negatively correlated with year-to-year variability. Additionally, the low-dimensional structure in river flow data correlated closely with only a small number of catchment characteristics, including catchment area, precipitation, and temperature—but notably not biome, dam surface area, or number of dams. We discuss these findings in a framework intended to be accessible to the many communities engaged in river research and management, while stressing the importance of letting structure in data guide both mechanistic inference and interdisciplinary discussion. © 2023. The optimal classifier for disease diagnosis by roc analysis

Item Type Journal Article

Author T. Zhang

Author W. Guo

Author G. Wang

Author X. Wang

Author Y. Zhang

Author W. Hong

Abstract Accuracy is commonly used as an index to evaluate the performance of classifiers. However, accuracy has several deficiencies, such as the sensitivity to class prior distribution and misclassification costs. Especially in the disease diagnosis, the classifier selected according to accuracy is not necessarily the optimal classifier. While the Receiver Operating Characteristic Curve (ROC) and the Area Under ROC (AUC) analysis technology are insensitive to the class distribution and different misclassification cost. Besides, they have advantages of direct-viewing, and easy to understand. This experiment is testing and analyzing the UCI datasets (Parkinson, diabetes, liver-disorder, breast-cancer) using different classifiers (LDC, KNNC, SVC), and comparing with the general indicator, to find out the optimal classifier to each group of data sets. At the same time, experiment shows the advantages of ROC and AUC in the evaluation of medical decision-making. © 2013 ISSN 2185-2766.

The potential for fuel reduction to reduce wildfire intensity in a warming California

Item Type Journal Article

Author P.T. Brown

Author S.J. Strenfel

Author R.B. Bagley

Author C.B. Clements

Abstract Increasing fuel aridity due to climate warming has and will continue to increase wildfire danger in California. In addition to reducing global greenhouse gas emissions, one of the primary proposals for counteracting this increase in wildfire danger is a widespread expansion of hazardous fuel reductions. Here, we quantify the potential for fuel reduction to reduce wildfire intensity using empirical relationships derived from historical observations with a novel combination of spatiotemporal resolution (0.375 km, instantaneous) and extent (48 million acres, 9 years). We use machine learning to quantify relationships between sixteen environmental conditions (including ten fuel characteristics and four temperature-affected aridity characteristics) and satellite-observed fire radiative power. We use the derived relationships to create fire intensity potential (FIP) maps for sixty historical weather snapshots at a 2 km and hourly resolution. We then place these weather snapshots in differing background climatological temperature and fuel characteristic conditions to quantify their independent and combined influence on FIP. We find that in order to offset the effect of climate warming under the SSP2-4.5 emissions scenario, fuel reduction would need to be maintained perpetually on ~3 million acres (or 600 000 acres per year, 1% of our domain, at a 5 year return frequency) by 2050 and ~8 million acres (or 1.6 million acres per year, 3% of our domain, at a 5 year return frequency) by 2090. Overall, we find substantial potential for fuel reduction to negate the effects of climate warming on FIP. © 2025 The Author(s). Published by IOP Publishing Ltd.

Abstract The prolonged latency period and delayed reporting of clinical surveillance data have led to a sluggish response to Bordetella pertussis outbreaks in China. Wastewater-based surveillance (WBS) provides real-time, cost-effective monitoring of various viruses. To confirm whether this approach can be applied to B. pertussis, 271 patients infected with B. pertussis were enrolled to evaluate the fecal shedding patterns of the bacterium. Concurrently, we collected wastewater samples in a typical northern (Xi'an) and southern city (Nanchang) in China, from September 2023 to July 2024. The concentrations of B. pertussis in the sewage were detected using quantitative polymerase chain reaction (qPCR). Additionally, metagenomic sequencing with pre-enrichment was employed to trace genotypes of B. pertussis. We report that 40.2% of cases tested positive for B. pertussis in fecal samples. Sewage surveillance identified two waves of B. pertussis infection in Xi'an and one wave of B. pertussis outbreak in

Nanchang. The concentration of *B. pertussis* in sewage showed a strong correlation with the dynamics of diagnosed cases. Notably, each peak of sewage *B. pertussis* concentration occurred 10 days prior to clinical surveillance, underscoring the value of WBS in early warning. Additionally, both clinical and wastewater surveillance demonstrated consistency in the prevalence estimation of *B. pertussis* infection cases. Finally, relative to clinical surveillance, wastewater sequencing also revealed the same genotypes of *B. pertussis*. This study presents the first comprehensive analysis of the fecal shedding of *B. pertussis*, thereby establishing the potential for early detection of *B. pertussis* outbreaks through WBS. © 2025 The Author(s). The prevalence of traumatic experiences and PTSD according to DSM-5 and ICD-11 in the German general population

Item Type Journal Article

Author A. Pettrich

Author Y. Nesterko

Author H. Glaesmer

Abstract Aims The Diagnostic and Statistical Manual of Mental Disorders - 5th Edition (DSM-5) and International Classification of Diseases - 11th Revision (ICD-11) employ different post-traumatic stress disorder (PTSD) criteria, necessitating updated prevalence estimates. Most of the existing evidence is still based on ICD-Tenth Revision and DSM-Fourth Edition criteria, leading to varied estimates across populations. This study provides current PTSD prevalence rates in the German general population, comparing DSM-5 and ICD-11 criteria and examines variations by age and gender. Methods In a 2016 cross-sectional survey of 2404 adults (18-94years) representative of the German general population, participants completed the Life-Events-Checklist for DSM-5 (LEC-5) for trauma exposure and the PTSD Checklist for DSM-5 (PCL-5) for PTSD symptoms. Probable PTSD diagnoses were based on DSM-5-, ICD-11-algorithms and suggested cut-off scores. Chi-square and McNemar's tests were used to test differences in prevalence rates by diagnostic framework, age and gender. Results Of the total sample, 47.2% (n=1135) reported experiencing at least one lifetime traumatic event (TE), with transportation accidents (7.3%) and life-threatening injuries (4.9%) being most common. Probable PTSD prevalence was 4.7% under both DSM-5 and ICD-11 criteria, and 2.6% based on a conservative cut-off normed for prevalence estimation. Gender and age were not significantly associated with TE exposure or PTSD prevalence, though trauma types varied: female participants more often reported sexual violence and severe suffering, while more male participants reported physical assaults and various types of accidents. DSM-5 and ICD-11 diagnostic algorithms had substantial yet not perfect agreement ($\kappa=0.62$). Particularly within the re-experiencing symptoms, cluster agreement was only moderate ($\kappa=0.57$). The cut-off method aligned more closely with DSM-5 ($\kappa=0.60$) than ICD-11 algorithm ($\kappa=0.42$). Conclusions This study provides updated PTSD prevalence estimates for the German general population and underscores differences between DSM-5 and ICD-11 in identifying cases, particularly with respect to re-experiencing symptoms. These findings emphasize that while overall PTSD prevalence rates under DSM-5 and ICD-11 criteria are similar, the diagnostic frameworks identify partially distinct cases, reflecting differences in

symptom definitions. This highlights the need to carefully consider the impact of evolving diagnostic criteria when interpreting prevalence estimates and comparing results across studies. © The Author(s), 2025. Published by Cambridge University Press.

The pulse waveform quantification method basing on contour and derivative

Item Type Journal Article

Author J. Jin

Author H. Zhang

Author X. Geng

Author Y. Zhang

Author T. Ye

Abstract Objective: Pulse waveform contains abundant physiological and pathological information. The condition of surrounding arteries can be reflected sensitively by the contour and derivative changes of pulse waves. In order to express these changes objectively, the pulse wave needs to be quantified. Methods: This study provides a novel quantification method for pulse waveform in the entire cardiac cycle. It involves two new quantification parameters k_1 and k_2 to display the waveform change caused by the superimposition of wave reflection in the systolic reflex period, which is the most significant changes period. In this method, multi parameters were fused by Kalman filter to obtain an optimal estimation, involving the new parameters and other parameters: k_0 for the early systolic period, C_1 and C_2 for diastole period, and K for pulse pressure. Results: Use correlation analysis to verify the effectiveness of new parameters that the coefficient is 0.7 between them and the typical augmentation index (AIx). The quantification results of 462 single-cycle pulse waves have consistent change trends with aging in 25–75 different age groups. For respiration analysis, the correlation coefficients are all greater than 0.6, even achieved 0.8 in six multi-cycle data between Kalman optimal estimation and breath wave. Conclusion: This method has quantified the waveform change with physiological status, and these quantification parameters can display the detail of each period. Significance: It will be used to verify waveform recognition accuracy and has a vast potential to detect diseases. © 2022 The Author(s)

The research on improved iterative control algorithm for maximum entropy model in electronic technology

Item Type Conference Paper

Author W. Yongqin

Author G. Yinjing

Author W. Na

Author Z. Rui

Abstract In the distributed processing, where common labeled data may be not available for designing classifier ensemble, however, an ensemble solution is necessary, traditional fixed decision aggregation could not account for class prior mismatch or classifier dependencies in electronic technology. Previous transductive learning strategies have several drawbacks, e.g., feasibility of the constraints was not guaranteed and heuristic learning was applied. We overcome these problems by developing improved iterative scaling (IIS) algorithm for optimal solution. This method is shown to achieve improved decision accuracy over the earlier approaches in electronic technology. © 2012 Springer-Verlag Berlin Heidelberg.

Abstract This paper outlines the winning solutions employed in addressing the MUAD uncertainty quantification challenge held at ICCV 2023. The challenge was centered around semantic segmentation in urban environments, with a particular focus on natural adversarial scenarios. The report presents the results of 19 submitted entries, with numerous techniques drawing inspiration from cutting-edge uncertainty quantification methodologies presented at prominent conferences in the fields of computer vision and machine learning and journals over the past few years. Within this document, the challenge is introduced, shedding light on its purpose and objectives, which primarily revolved around enhancing the robustness of semantic segmentation in urban scenes under varying natural adversarial conditions. The report then delves into the top-performing solutions. Moreover, the document aims to provide a comprehensive overview of the diverse solutions deployed by all participants. By doing so, it seeks to offer readers a deeper insight into the array of strategies that can be leveraged to effectively handle the inherent uncertainties associated with autonomous driving and semantic segmentation, especially within urban environments. © 2023 IEEE.

The Robustness of the gray level co-occurrence matrices and x-ray computed tomography method for the quantification of 3d mineral texture

Item Type Journal Article

Author M. Voigt

Author J.A. Miller

Author A.N. Mainza

Author L.C. Bam

Author M. Becker

Abstract Mineral textural quantification methods have become critical in both geosciences and mineral processing as mineral texture is a critical factor contributing to ore variability. However, the lack of objective mineral texture classification has made quantification difficult. The aim of this study is therefore to investigate the robustness of applying the gray level co-occurrence matrices (GLCM) to 3-dimensional (3D) gray scale images measured by X-ray computed tomography (XCT) for the quantification of mineral texture in 3D. The data quality of the GLCM outputs like statistics, heat maps and histograms in response to changes in XCT conditions such as artefacts, resolution, and calibration was tested. The response of the GLCM outputs with respect to different mineral texture types with anisotropic features and inter-sample variability was also explored. The methodology included testing core sizes of 26, 19, 14, and 6 mm diameter. Calibration was tested using copper and tungsten wires. The study demonstrated the versatility of the method for different sample types. Inter-sample calibration and optimal scanning conditions (quality and integrity) were also demonstrated, and a basic link between the 3D GLCM statistical descriptors with the mineral texture features of rocks was established. The 3D mineral texture method can potentially bypass the XCT segmentation process for direct automation of 3D mineral texture information. © 2020 by the authors. Licensee MDPI, Basel, Switzerland.

The role of prior and optimal team decision in binary classification

Item Type Conference Paper

Author K. Krishnamoorthy

Author M. Pachter

Abstract Optimal team decision making subject to error-prone team members with different capabilities has been studied extensively - particularly in the context of binary classification. The over-arching goal is to correctly classify an object as either being a True Target or a False Target. Each team member comes with pre-specified Type I and II error rates and is asked whether or not he determines the object to be a True Target. Based on the member responses, a collective decision that minimizes the probability of misclassification (or some other suitable metric) is made. This is a widely researched topic, having applications in pattern recognition, organizational decision making, social (dichotomous) choice situations, reliability studies etc.; however, in past work, the obvious connection to information theory is missing. In this work, we establish the optimal team decision rules that minimizes the probability of misclassification, by direct application of Bayesian decision theory. In doing so, we bring out the key role played by the a priori probability (prior) that the object is a True Target. In particular, for a homogeneous team composition, we establish the criteria whence the majority voting scheme is indeed optimal. Whereupon, it immediately follows that the higher the prior, the fewer the number of affirmative votes needed to classify the object as a True Target. © 2016 American Automatic Control Council (AACC).

The Role of Uncertainty Quantification for Trustworthy AI

Item Type Journal Article

Author J. Deuschel

Author A. Foltyn

Author K. Roscher

Author S. Scheele

Abstract The development of AI systems involves a series of steps, including data acquisition and preprocessing, model selection, training, evaluation, and deployment. However, each of these steps involves certain assumptions that introduce inherent uncertainty, which can result in inaccurate outcomes and reduced confidence in the system. To enhance confidence and comply with the EU AI Act, we recommend using Uncertainty Quantification methods to estimate the belief in the correctness of a model's output. To make these methods more accessible, we provide insights into the possible sources of uncertainty and offer an overview of the different available methods. We categorize these methods based on when they are used in the process, accounting for various application requirements. We distinguish between three types: data-based, architecture-modifying and post-hoc methods, and share our personal experiences with each.

Author P. Zhou

Abstract Background: There is no consensus on 3-dimensional (3D) quantification method for solid component within part-solid nodules (PSNs). This study aimed to find the optimal attenuation threshold for the 3D solid component proportion in low-dose computed tomography (LDCT), namely the consolidation/tumor ratio of volume (CTRV), basing on its correlation with the malignant grade of nonmucinous pulmonary adenocarcinomas (PAs) according to the 5th edition of World Health Organization classification. Then we tested the ability of CTRV to predict high-risk nonmucinous PAs in PSNs, and compare its performance with 2-dimensional (2D) measures and semantic features. Methods: A total of 313 consecutive patients with 326 PSNs, who underwent LDCT within one month before surgery and were pathologically diagnosed with nonmucinous PAs, were retrospectively enrolled and were divided into training and testing cohorts according to scanners. The CTRV were automatically generated by setting a series of attenuation thresholds from – 400 to 50

HU with an interval of 50 HU. The Spearman's correlation was used to evaluate the correlation between the malignant grade of nonmucinous PAs and semantic, 2D, and 3D features in the training cohort. The semantic, 2D, and 3D models to predict high-risk nonmucinous PAs were constructed using multivariable logistic regression and validated in the testing cohort. The diagnostic performance of these models was evaluated by the area under curve (AUC) of receiver operating characteristic curve. Results: The CTRV at attenuation threshold of -250 HU (CTRV- 250HU) showed the highest correlation coefficient among all attenuation thresholds ($r = 0.655$, $P < 0.001$), which was significantly higher than semantic, 2D, and other 3D features (all $P < 0.001$). The AUCs of CTRV- 250HU to predict high-risk nonmucinous PAs were 0.890 (0.843–0.927) in the training cohort and 0.832 (0.737–0.904) in the testing cohort, which outperformed 2D and semantic models (all $P < 0.05$). Conclusions: The optimal attenuation threshold was - 250 HU for solid component volumetry in LDCT, and the derived CTRV- 250HU might be valuable for the risk stratification and management of PSNs in lung cancer screening. © 2023, The Author(s).

Abstract Facial movements are crucial for social and emotional interaction and well-being. Reduced facial expressions (i.e., hypomimia) is a common feature in patients with Parkinson’s disease (PD) and previous studies linked this manifestation to both motor symptoms of the disease and altered emotion recognition and processing. Nevertheless, research on facial motor impairment in PD has been rather scarce and only a limited number of clinical evaluation tools are available, often suffering from poor validation processes and high inter- and intra-rater variability. In recent years, the availability of technology-enhanced quantification methods of facial movements, such as automated video analysis and machine learning application, led to increasing interest in studying hypomimia in PD. In this narrative review, we summarize the current knowledge on pathophysiological hypotheses at the basis of hypomimia in PD, with particular focus on the association between reduced facial expressions and emotional processing and analyze the current evaluation tools and management strategies for this symptom, as well as future research perspectives. © 2024 by the authors.

The structure of dual Grassmann codes

Item Type Journal Article

Author P. Beelen

Author F. Piñero

Abstract In this article we study the duals of Grassmann codes, certain codes coming from the Grassmannian variety. Exploiting their structure, we are able to count and classify all their minimum weight codewords. In this classification the lines lying on the Grassmannian variety play a central role. Related codes, namely the affine Grassmann codes, were introduced more recently in Beelen et al. (IEEE Trans Inf Theory 56(7):3166–3176, 2010), while their duals were introduced and studied in Beelen et al. (IEEE Trans Inf Theory 58(6):3843–3855, 2010). In this paper we also classify and count the minimum weight codewords of the dual affine Grassmann codes. Combining the above classification results, we are able to show that the dual of a Grassmann code is generated by its minimum weight codewords. We use these properties to establish that the increase of value of successive generalized Hamming weights of a dual Grassmann code is 1 or 2. © 2015, Springer Science+Business

The use of detailed biotope data for linking biodiversity with ecosystem services in Finland

Item Type Journal Article

Author P. Vihervaara

Author T. Kumpula

Author A. Ruokolainen

Author A. Tanskanen

Author B. Burkhard

Abstract It has been widely accepted that ecosystem services (ESs) should be taken into account in natural resource management decisions. Hence, there is an increasing need for innovative quantification methods and tools to evaluate ESs on different landscape scales, and under varying land-use forms. Integrating biodiversity

protection with the provision of ESs is a key element for sustainable land-use planning. Geographic Information Systems (GIS) and spatial analysis, together with various environmental data, provide a suitable foundation for ESs evaluations. Recent advances in earth observation technologies have supported land-cover-based ESs mapping on global, regional and local scales. Global and regional land-cover maps can help in coarse assessments of some biophysical characteristics of the environment, but they cannot provide exact information about local biodiversity and biotope types that form the base of ESs supply. Therefore, more detailed tools such as aerial photographs and field surveys are needed. High-quality biotope data are usually fragmentary or absent for private land in Finland, but are available for most state-owned commercial forests and protection areas. We tested the use of biotope data derived from aerial photographs and an extensive field inventory to map ESs in natural protection areas in northern Finland. We argue that protection areas, where large and long-term databases have been collected, offer excellent study sites to develop further the methodology for integrating coarse-scale remote-sensing data, such as CORINE, with more detailed ecological and structural data collected from aerial photographs and ground surveys. In addition, the use of detailed biotope data supports the linkage of biodiversity information with landscapes' capacities to provide ESs. Different data sources will improve the management of protection areas, thereby optimizing multiple land-use objectives. © 2012 Taylor & Francis.

The use of machine learning for inverse uncertainty quantification in TRACE code based on Marviken experiment

Item Type Journal Article

Author P. Domitr

Author M. Włostowski

Abstract Inverse Uncertainty Quantification (IUQ) methods are gaining recognition in the application of Best Estimate Plus Uncertainty methodologies. Typically, the code input parameters constituted the sources of uncertainties that cannot be estimated other than by user expertise. The IUQ methods aim at providing a more robust and scientific estimation of the distributions of those parameters. In this paper, an approach has been proposed to use machine learning to quantify the uncertainty of critical flow parameters available in the TRACE code. Serving as the means to the ultimate goal of IUQ, the machine learning algorithm has also been utilized in the qualitative assessment of discrepancies between the experiment and calculations. First, a set of Monte Carlo calculations were performed for selected Marviken Critical Flow Tests with permutated values of input parameters of TRACE code. Then, utilizing a supervised machine learning model and a set of features describing the mass flow progression, a Random Forest classifier was used to assign the results to one of the defined classes of prediction accuracy. This analysis has been done using two different training datasets to present the influence of the training data selection on the classification. The machine learning classification resulted in creating a class for which the results with the best fit to the experiment were collected. Derivation of this class created an opportunity to propose ranges and probability distribution functions for CHM12 and CHM22 TRACE internal variables, which is a goal for IUQ methods. Lognormal distribution has been proposed for CHM12 with a mode equal to 0.87, while normal distribution was proposed for CHM22 with a mean equal to 0.9. Variables C1RC2 and C2RC2 proved to be uninfluential on the results. The PDFs for CHM12 and CHM22 have been verified on all 26 Marviken tests. The article proposes a method that can be used in best-estimate analyses to obtain reliable distributions of input variables. © 2021 Elsevier B.V.

The washing system based on RFID research

Item Type Conference Paper

Author Z. Yajuan

Author W. Jun

Author R. Hongwei

Author H. Yan

Author Z. Yong

Abstract Hospital has huge amount of bedding and clothing usages and complicated processes in cleaning and disinfection, some even have special requirements in the process of cleaning and transportation such as a separate isolation to prevent pollution. Nowadays, hospital bedding and clothing inventory and classification are mainly done by manual operation, it is hard to avoid cross-contamination in the unpack process, at the same time the manual counting cost large amount of labor but has low accuracy and efficiency. To avoid secondary pollution as well as cross-contamination and improve the counting efficiency and accuracy, we can use RFID (Radio Frequency Identification) chips to identify the bedding and clothing to realize the automatic counting function during transportation. This paper describes an automatic clothing inventory and classification system dependent on a ultra-high frequency (UHF) RFID chip, which can automatically classify and count the clothes, record washing, disinfection and transportation processes and usage condition of clothes through cloud server. Besides, it can also support the remote tracking, fee settlement of clothing cleaning, and disinfection and transportation. These processes can be performed by handheld devices and special devices. It makes hospital clothing cleaning, disinfection and transportation become traceable. © 2015 IEEE.

The Youth Online Exploitation–Extremism Interface: A Conceptual Framework for Anti-Trafficking Identification and Digital Child Protection

Item Type Journal Article

Author H.N. Landress

Abstract Technology-facilitated child sexual exploitation increasingly intersects with coercive digital abuse and violent online subcultures that reward humiliation, self-harm, and abuse-material production as status markers. Conventional anti-trafficking identification is poorly suited to these cases, where exploitation operates through image-based leverage, reputational control, and platform migration rather than physical transportation or confinement. This Brief Report introduces the Youth Online Exploitation–Extremism Interface Framework, a conceptual-practice model with seven interacting domains: youth vulnerability, digital access points, coercive mechanisms, abuse-material production, group and status reinforcement, violence-aesthetic overlay, and response pathways. The domains are analytically separable but empirically entangled and recursive, so information in one domain can revise interpretation of another. The framework draws on 174 publicly documented incidents (2014 to 2026) in the PERIL Nihilistic Violent Extremism Tracker, serving as illustrative anchors rather than a representative sample for prevalence estimation. It supports identification, documentation, and survivor-centered referral across anti-trafficking, child protection, school safety, and survivor-serving settings. It is not a legal trafficking test, extremism classification, or risk-prediction instrument. Contribution to UN Sustainable Development Goals. This report supports UN

Sustainable Development Goal 16, Target 16.2 (ending abuse, exploitation, trafficking, and violence against children). By giving anti-trafficking, child-protection, school-safety, and platform-safety practitioners a shared vocabulary for trafficking-adjacent online exploitation in violent online subcultures, the framework can improve early identification, documentation, and survivor-centered referrals. It also contributes to SDG 5 (Target 5.2, eliminating violence and exploitation against women and girls), foregrounding youth-facing sexual coercion and image-based sexual abuse as distinct yet co-occurring harms requiring a multi-system response. © 2026 Taylor & Francis Group, LLC.

Abstract In PU learning, a binary classifier is trained from positive (P) and unlabeled (U) data without negative (N) data. Although N data is missing, it sometimes outperforms PN learning (i.e., ordinary supervised learning). Hitherto, neither theoretical nor experimental analysis has been given to explain this phenomenon. In this paper, we theoretically compare PU (and NU) learning against PN learning based on the upper bounds on estimation errors. We find simple conditions when PU and NU learning are likely to outperform PN learning, and we prove that, in terms of the upper bounds, either PU or NU learning (depending on the class-prior probability and the sizes of P and N data) given infinite U data will improve on PN learning. Our theoretical findings well agree with the experimental results on artificial and benchmark data even when the experimental setup does not match the theoretical assumptions exactly. © 2016 NIPS Foundation - All Rights Reserved.

Theoretical insights into multiclass classification: A high-dimensional asymptotic view

Item Type Conference Paper

Author C. Thrampoulidis

Author S. Oymak

Author M. Soltanolkotabi

Abstract Contemporary machine learning applications often involve classification tasks with many classes. Despite their extensive use, a precise understanding of the statistical properties and behavior of classification algorithms is still missing, especially in modern regimes where the number of classes is rather large. In this paper, we take a step in this direction by providing the first asymptotically precise analysis of linear multiclass classification. Our theoretical analysis allows us to precisely characterize how the test error varies over different training algorithms, data distributions, problem dimensions as well as number of classes, inter/intra class correlations and class priors. Specifically, our analysis reveals that the classification accuracy is highly distribution-dependent with different algorithms achieving optimal performance for different data distributions and/or training/features sizes. Unlike linear regression/binary classification, the test error in multiclass classification relies on intricate functions of the trained model (e.g., correlation between some of the trained weights) whose asymptotic behavior is difficult to characterize. This challenge is already present in simple classifiers, such as those minimizing a square loss. Our novel theoretical techniques allow us to overcome some of these challenges. The insights gained may pave the way for a precise understanding of other classification algorithms beyond those studied in this paper. © 2020 Neural information processing systems foundation. Thermal bridging in buildings: A critical review of mechanisms, mitigation strategies, energy impacts, and research needs

Item Type Journal Article

Author M. Ahsan

Author M.A. Youssef

Author C. Van Dongen

Author D. Thompson

Author G. Stanier

Abstract The increasingly stringent energy and emission targets have made thermal bridging a critical consideration for building construction. Thermal bridging is excessive, localized heat flow through discontinuities in the insulation layer, such as at window and door assemblies, building envelope junctions, or balconies, that significantly increases space-heating and cooling demand, depresses interior surface temperatures, and promotes moisture-related durability problems. This paper presents a state-of-the-art critical review of thermal bridging in buildings, with emphasis on its mechanisms, quantification, and mitigation. The classifications, causes, and locations of thermal bridges within the building envelope are synthesized, and methods for evaluating them, including the Equivalent Wall Method (EWM), the Equivalent U-Value Method (EUVM), and 2D/3D numerical modelling, are compared. Element-specific mitigation strategies for openings, exposed structural components, walls, junctions, and balconies are reviewed, highlighting their influence on effective envelope R-values, building energy use, and condensation risk. The literature shows that thermal bridges account for a substantial fraction of heat loss in highly insulated buildings and become proportionally more important as envelope requirements tighten. Key knowledge gaps are identified, including the scarcity of long-term experimental validation and the need for holistic, constructible solutions that integrate structural, architectural, and thermal performance. Practical Application: Thermal bridging can materially affect heating and cooling loads, interior surface temperatures, and moisture risk in high-performance envelopes. This review provides building professionals with a comprehensive foundation to identify high-impact details (openings, slab edges, balconies, and junctions), select appropriate quantification methods (Ψ/χ values, EUVM, and 2D/3D modelling) for design and compliance, and prioritize constructible mitigation strategies, such as, but not limited to, continuous insulation, thermally broken connections, and improved detailing and quality control. The review supports a more holistic, durability-focused decision-making process through efficient HVAC system sizing and smart envelope design. © The Author(s) 2026. THREATENING DEGREE ASSESSMENT METHOD OF SONAR TARGETS BASED ON MULTI-SOURCE INFORMATION FUSION

Item Type Conference Paper

Author B. Zhou

Author X. Song

Author Q. Wang

Author Y. Chen

Editor Papadakis J.S.

Abstract Multi-source information fusion can expand the detection range of a sonar system and improve the reliability and robustness of target recognition. To solve the problems of large transmission bandwidth, uncertain priori probability of target threatening degree discrimination, and inability to perform fusion processing within the framework of probability theory in the sonar target association using full spectrum feature information, a threatening degree assessment method for sonar targets based on multi-source information fusion is proposed in this paper. The method combines the target information output from low-frequency array, high-frequency array and non-acoustic sensor, to perform threatening degree assessment of low-frequency sonar target through multi-source information preprocessing, target track association, association information fusion and target classification. For target track association, an improved gray association algorithm is proposed, which can distinguish two different targets with the same track change trend but far away from each other. In the absence of a priori probability of threatening target discrimination, a multi-source information fusion method based on Dempster-Shafer evidence theory is proposed to solve the problem that probability theory cannot be effectively applied to information fusion processing, so as to eliminate non-threatening targets. Finally the Template matching technique is used to further improve the accuracy of target threatening degree assessment. The proposed method is verified by sea trial data of multi-source information, including low-frequency array data, high-frequency array data and automatic identification system(AIS) data. This work can meet the needs of low-frequency sonar target threatening degree assessment. © 2019, I.A.C.M, Foundation for Research and Technology - Hellas. All rights reserved.

Abstract Background Echocardiographic determination of left heart chamber volumetric parameters by using manual tracings during multiple beats is tedious in atrial fibrillation (AF). The aim of this study was to determine the usefulness of fully automated left chamber quantification software with single-beat three-dimensional transthoracic echocardiographic data sets in patients with AF. Methods Single-beat full-volume three-dimensional transthoracic echocardiographic data sets were prospectively acquired during consecutive multiple cardiac beats (≥ 10 beats) in 88 patients with AF. In protocol 1, left ventricular volumes, left ventricular ejection fraction, and maximal left atrial volume were validated using automated quantification against the manual tracing method in identical beats in 10 patients. In protocol 2, automated quantification-derived averaged values from multiple beats were compared with the corresponding values obtained from the indexed beat in all patients. Results Excellent correlations of left chamber parameters between automated quantification and the manual method were observed ($r = 0.88\text{--}0.98$) in protocol 1. The time required for the analysis with the automated quantification method (5 min) was significantly less compared with the manual method (27 min) ($P < .0001$). In protocol 2, there were excellent linear correlations between the averaged left chamber parameters and the corresponding values obtained from the indexed beat ($r = 0.94\text{--}0.99$), and test-retest variability of left chamber parameters was low (3.5%–4.8%). Conclusions Three-dimensional transthoracic echocardiography with fully automated quantification software is a rapid and reliable way to measure averaged values of left heart chamber parameters during multiple consecutive beats. Thus, it is a potential new approach for left chamber quantification in patients with AF in daily routine practice. © 2016 American Society of Echocardiography

Abstract Objective: Quantification of angiographic images with two-photon laser scanning fluorescence microscopy (2PLSM) relies on proper segmentation of the vascular images. However, the images contain inhomogeneities in the signal-to-noise ratio (SNR) arising from regional effects of light scattering and absorption. The present study developed a semiautomated quantification method for volume images of 2PLSM angiography by adjusting the binarization threshold according to local SNR along the vessel centerlines. Methods: A phantom model made with fluorescent microbeads was used to incorporate a region-dependent binarization threshold. Results: The recommended SNR for imaging was found to be 4.2–10.6 that provide the true size of imaged objects if the binarization threshold was fixed at 50% of SNR. However, angiographic images in the mouse cortex showed variable SNR up to 45 over the depths. To minimize the errors caused by variable SNR and a spatial extent of the imaged objects in an axial direction, the microvascular networks were three-dimensionally reconstructed based on the cross-sectional diameters measured along the vessel centerline from the XY-plane images with adapted binarization threshold. The arterial volume was relatively constant over depths of 0–500 μm , and the capillary volume (1.7% relative to the scanned volume) showed the larger volumes than the artery (0.8%) and vein (0.6%). Conclusions: The present methods allow consistent segmentation of microvasculature by adapting the local inhomogeneity in the SNR, which will be useful for quantitative comparison of the microvascular networks, such as under disease conditions where SNR in the 2PLSM images varies over space and time. © 2021 John Wiley & Sons Ltd

Abstract The objective of this study was to assess the implementation of a three-year *Mycobacterium avium* subsp. paratuberculosis monitoring programme using pooled faecal culture in small and medium-sized dairy herds to classify them as infected or non-infected and apply proper hygiene and biosecurity measures. Over a three-year period, 35 dairy herds were analysed annually by faecal culture of ten pooled samples. In addition, proper hygiene and biosecurity protocols were implemented in the farms after the first testing round. Considering a herd as infected with at least one culture positive in any of the three years, the accumulated percentage of infected herds was 25.7%, 40% and 45.7%, for each year respectively. Assuming that all infected herds had been detected at the end of the study, the percentage of infected

herds detected each year was 56.25% and 87.5% for the first and second year, respectively. Using frequentist and Bayesian approaches, the estimated individual prevalence revealed a downward trend from 3.30-3.65% in the first year to 1.66-1.86% in the third year. The results of this study indicate that pooled faecal culture allowed for proper classification of the herds and can be a useful tool for monitoring dairy herds against paratuberculosis. In addition, statistical analysis of pooled faecal culture results can be used to evaluate the evolution of individual prevalence in the population and therefore the function of the implemented control programmes. © Walter de Gruyter GmbH 2018. Threshold optimization and random undersampling for imbalanced credit card data

Item Type Journal Article

Author J.L. Leevy

Author J. Hancock

Author T.M. Khoshgoftaar

Abstract Output thresholding is well-suited for addressing class imbalance, since the technique does not increase dataset size, run the risk of discarding important instances, or modify an existing learner. Through the use of the Credit Card Fraud Detection

Dataset, this study proposes a threshold optimization approach that factors in the constraint True Positive Rate (TPR) $\geq$ True Negative Rate (TNR). Our findings indicate that an increase of the Area Under the Precision–Recall Curve (AUPRC) score is associated with an improvement in threshold-based classification scores, while an increase of positive class prior probability causes optimal thresholds to increase. In addition, we discovered that best overall results for the selection of an optimal threshold are obtained without the use of Random Undersampling (RUS). Furthermore, with the exception of AUPRC, we established that the default threshold yields good performance scores at a balanced class ratio. Our evaluation of four threshold optimization techniques, eight threshold-dependent metrics, and two threshold-agnostic metrics defines the uniqueness of this research. © 2023, The Author(s).

Abstract Background: Conventional fat quantification methods for rotator cuff muscles have various limitations, such as inconsistent reliabilities of the Goutallier grades and need for advanced techniques in quantitative MRI sequences. We aimed to examine a threshold-based fat quantification method in the supraspinatus muscle on standard T1-weighted MR images and compare the threshold-based method with Goutallier grades and MR spectroscopy. Methods: We retrospectively examined 38 symptomatic patients, who underwent T1 and T2-weighted fast spin-echo MR imaging and a single voxel spin-echo MR spectroscopy. The supraspinatus muscle and fossa were manually segmented in T1-weighted sagittal images and clustering-based thresholding was applied to quantify the fat fractions in the segmented areas using custom MATLAB software. Threshold-based fat fractions were compared with the Goutallier grades and MR spectroscopy fat/water ratios. A one-way analysis of variance and Pearson correlation were tested in the MATLAB software. Results: Inter-observer reliability of threshold-based fat fractions for the supraspinatus muscle and fossa were 0.977 and 0.990 respectively, whereas the reliability of the Goutallier grading was 0.798. Threshold-based fat fractions in the supraspinatus fossa were significantly different between various Goutallier grades (one-way ANOVA, $p < 0.001$). Threshold-based fat fractions in the supraspinatus muscle strongly correlated with the MR spectroscopy fat/water ratio (Pearson correlation R-square = 0.83). Conclusions: Threshold-based fat quantification on standard T1-weighted MR images was highly reliable and produced comparable results to conventional Goutallier grades and MR spectroscopy fat/water ratios and could serve as an alternative method for accurate fat quantification in rotator cuff muscles. © 2020 The Author(s).

Thresholding strategies for deep learning with highly imbalanced big data

Item Type Journal Article

Author J.M. Johnson

Author T.M. Khoshgoftaar

Abstract A variety of data-level, algorithm-level, and hybrid methods have been used to address the challenges associated with training predictive models with class-imbalanced data. While many of these techniques have been extended to deep neural network (DNN) models, there are relatively fewer studies that emphasize the significance of output thresholding. In this chapter, we relate DNN outputs to Bayesian a posteriori probabilities and suggest that the Default threshold of 0.5 is almost never optimal when training data is imbalanced. We simulate a wide range of class imbalance levels using three real-world data sets, i.e. positive class sizes of 0.03–90%, and we compare Default threshold results to two alternative thresholding strategies. The Optimal threshold strategy uses validation data or training data to search for the classification threshold that maximizes the geometric mean. The Prior threshold strategy requires no optimization, and instead sets the classification threshold to be the prior probability of the positive class. Multiple deep architectures are explored and all experiments are repeated 30 times to account for random error. Linear models and visualizations show that the Optimal threshold is strongly correlated with the positive class prior. Confidence intervals show that the Default threshold only performs well when training data is balanced and Optimal thresholds perform significantly better when training data is skewed. Surprisingly, statistical

results show that the Prior threshold performs consistently as well as the Optimal threshold across all distributions. The contributions of this chapter are twofold: (1) illustrating the side effects of training deep models with highly imbalanced big data and (2) comparing multiple thresholding strategies for maximizing class-wise performance with imbalanced training data. © 2021, The Editor(s) (if applicable) and The Author(s), under exclusive license to Springer Nature Singapore Pte Ltd.

Abstract Common prototype-based medical image few-shot segmentation (FSS) methods model foreground and background classes using class-specific prototypes. However, given the high variability of the background, a more promising direction is to focus solely on foreground modeling, treating the background as an anomaly—an approach introduced by ADNet. Yet, ADNet faces three key limitations: dependence on a single prototype per class, a focus on binary classification, and fixed thresholds that fail to adapt to patient and organ variability. To address these shortcomings, we propose the Tied Prototype Model (TPM), a principled reformulation of ADNet with tied prototype locations for foreground and background distributions. Building on its probabilistic foundation, TPM naturally extends to multiple prototypes and multi-class segmentation while effectively separating non-typical background features. Notably, both extensions lead to improved segmentation accuracy. Finally, we leverage naturally occurring class priors to define an ideal target for adaptive thresholds, boosting segmentation performance. Taken together, TPM provides a fresh perspective on prototype-based FSS for medical image segmentation. The code can be found at <https://github.com/hjk92g/TPM-FSS>. © The Author(s), under exclusive license to Springer Nature Switzerland AG 2026.

Author T. Hengl

Abstract The production and evaluation of the analysis-ready and cloud-optimized (ARCO) data cube for continental Europe (including Ukraine, the UK, and Türkiye), derived from the Landsat analysis-ready dataset version 2 (ARD V2) produced by Global Land Analysis and Discovery (GLAD) team and covering the period from 2000 to 2022, is described. The data cube consists of 17 TB of data at a 30 m resolution and includes bimonthly, annual, and long-term spectral indices on various thematic topics, including surface reflectance bands, normalized difference vegetation index (NDVI), soil adjusted vegetation index (SAVI), fraction of absorbed photosynthetically active radiation (FAPAR), normalized difference snow index (NDSI), normalized difference water index (NDWI), normalized difference tillage index (NDTI), minimum normalized difference tillage index (minNDTI), bare soil fraction (BSF), number of seasons (NOS), and crop duration ratio (CDR). The data cube was developed with the intention to provide a comprehensive feature space for environmental modeling and mapping. The quality of the produced time series was assessed by (1) assessing the accuracy of gap-filled bimonthly Landsat data with artificially created gaps; (2) visual examination for artifacts and inconsistencies; (3) plausibility checks with ground survey data; and (4) predictive modeling tests, examples with soil organic carbon (SOC) and land cover (LC) classification. The time series reconstruction demonstrates high accuracy, with a root mean squared error (RMSE) smaller than 0.05, and R2 higher than 0.6, across all bands. The visual examination indicates that the product is complete and consistent, except for winter periods in northern latitudes and high-altitude areas, where high cloud and snow density introduce significant gaps and hence many artifacts remain. The plausibility check further shows that the indices logically and statistically capture the processes. The BSF index showed a strong negative correlation (−0.73) with crop coverage data, while the minNDTI index had a moderate positive correlation (0.57) with the Eurostat tillage practice survey data.

The detailed temporal resolution and long-term characteristics provided by different tiers of predictors in this data cube proved to be important for both soil organic carbon regression and LC classification experiments based on 60 723 LUCAS observations: long-term characteristics (tier 4) were particularly valuable for predictive mapping of SOC and LC, coming out on top of variable importance assessment. Crop-specific indices (NOS and CDR) provided limited value for the tested applications, possibly due to noise or insufficient quantification methods. The data cube is made available at <https://doi.org/10.5281/zenodo.10776891> (Tian et al., 2024) under a CC-BY license and will be continuously updated. © 2025 Xuemeng Tian et al.

Time-Aware Crime Prediction: A Multi-Output AI Framework for Operational Risk Prioritization

Item Type Journal Article

Author C. Eroglu

Author H. Cakir

Abstract This study proposes an artificial intelligence (AI)-supported operational crime prediction framework that integrates temporal, spatial, and harm-aware risk modeling for short-term operational prioritization. Unlike conventional binary crime prediction

approaches, the proposed multi-output framework simultaneously estimates crime occurrence probability, expected crime volume, crime harm, and crime category. Experimental results demonstrate that the joint use of temporal and spatial features substantially improves predictive performance, increasing Precision-Recall Area Under the Curve (PR-AUC) from 0.1849 to 0.2346 despite severe class imbalance (positive-class prevalence = 0.0715), while Receiver Operating Characteristic Area Under the Curve (ROC-AUC) improved from 0.7236 to 0.7496. The stacking approach produced more balanced and generalizable performance compared to individual models. The framework also exhibited strong probabilistic calibration, achieving an Expected Calibration Error (ECE) of 0.0012 and a Brier score of approximately 0.06. The multi-output modules further achieved $RMSE \approx 0.445$ for expected crime count estimation and $RMSE \approx 4.02$ for expected harm prediction. Under realistic operational evaluation settings, the model achieved precision@500 of 0.7460, precision@5000 of 0.5418, and lift@5000 of 7.57, while maintaining stable performance under strict out-of-fold and rolling as-of backtesting conditions (PR-AUC ≈ 0.260 and PR-AUC ≈ 0.251 , respectively). The findings indicate that the proposed framework provides both improved predictive capability and practical utility for operational risk prioritization and decision-support processes in short-term crime forecasting. © 2013 IEEE.

Abstract Uncertainty quantification (UQ) is a prominent approach for eliciting truthful answers from large language models (LLMs). To date, information-based and consistency-based UQ have been the dominant UQ methods for text generation via LLMs. Density-based methods, despite being very effective for UQ in text classification with encoder-based models, have not been very successful with generative LLMs. In this work, we adapt Mahalanobis Distance (MD) - a well-established UQ technique in classification tasks - for text generation and introduce a new supervised UQ method. Our method extracts token embeddings from multiple layers of LLMs, computes MD scores for each token, and uses linear regression trained on these features to provide robust uncertainty scores. Through extensive experiments on eleven datasets, we demonstrate that our approach substantially improves over existing UQ methods, providing accurate and computationally efficient uncertainty scores for both sequence-level selective generation and claim-level fact-checking tasks. Our method also exhibits strong generalization to out-of-domain data, making it suitable for a wide range of LLM-based applications. © 2025 Association for Computational Linguistics.

Tomato Health Monitoring System: Tomato Classification, Detection, and Counting System Based on YOLOv8 Model With Explainable MobileNet Models Using Grad-CAM++

Item Type Journal Article

Author L.-D. Quach

Author K.N. Quoc

Author A.N. Quynh

Author H.T. Ngoc

Author N. Thai-Nghe

Abstract Fruits and vegetables (especially, tomatoes) healthy detection are important tasks for smart agriculture. Several works have been published in tomato detection, however, there is little research on using explainable AI to detect, classify and count tomato fruit status. In this work, we propose a Tomatoes Health Check System by evaluating MobileNet models based on the physiological tomato dataset. Our research conducts experiments to evaluate the accuracy of the MobileNets, MobileNetV2 and MobileNetV3 models based on the evaluation metrics; the highest accuracy of 96.69% belongs to the MobileNetV3 model. The proposed method we suggest is to utilize Grad-CAM++ for a visual explanation of predictions made by models belonging to the MobileNets family. Subsequently, we calculate Intersection over Union metrics at various thresholds (0%, 25%, and 50%) based on each heatmap or region of importance. To assess model reliability, Grad-CAM++ is used to explain and evaluate reliability, with MobileNetV2 achieving the highest values at 100.00% (d=0), 100.00% (d=0.25), and 98.89% (d=0.5). An evaluation experiment combines the YOLOv8 and MobileNetV2 algorithms using the Simple Online and Real-time Tracking (SORT) algorithm to detect, classify, and count tomatoes based on physiological characteristics in videos. Finally, the research results are utilized to develop an application system. © 2013 IEEE.

Tools for Analyzing Signature-Based Hardware Solutions for Cyber Security Systems

Item Type Journal Article

Author S.Ya. Hilgurt

Author A.M. Davydenko

Author T.V. Matovka

Author M.P. Prygara

Abstract When creating signature-based cybersecurity systems for network intrusion detection (NIDS), spam filtering, protection against viruses, worms, etc., developers have to use hardware devices such as field programmable gate arrays (FPGA), since software solutions can no longer support the necessary speeds. There are many different approaches to build hardware circuits for pattern matching (where patterns are the parts of signatures). Choosing the optimal technical solution for certain conditions is not a trivial task. Developers of such hardware tend to act intuitively, heuristically. In this article, we provide tools to help them intelligently build cybersecurity systems using FPGAs. For the qualitative analysis of FPGA-based matching schemes, the classification of efficiency criteria and related indicators is considered. This classification was compiled by studying a large number of practical developments of FPGA-based cybersecurity systems, primarily NIDS. A method of rapid calculating numerical characteristics of the FPGA-based signature system components is

proposed as a quantitative assessment tool. This method based on the use of so-called estimation functions allows avoiding the time-consuming execution of the digital circuit synthesis procedure. A number of experiments were carried out with the most promising matching schemes, allowing evaluating the above-mentioned tools. The rapid quantification method allows developers of hardware-accelerated cybersecurity systems to even apply it at each iteration within the optimization procedure cycle. © 2023 River Publishers.

Tooth segmentation in mixed dentition CBCT via a three-stage class-prior and morphology-aware framework

Item Type Journal Article

Author J. Zhang

Author X. Li

Author Y. Hu
Author W. Tang
Author X. Wang
Author J. Guo

Abstract Accurate three-dimensional (3D) tooth segmentation in pediatric cone-beam computed tomography (CBCT) scans remains challenging during the mixed dentition stage due to its complex anatomical characteristics. Existing methods designed for permanent dentition often fail to generalize effectively, primarily owing to the increased number of teeth, crowding, intricate spatial arrangements, and significant morphological variations inherent to mixed dentition. To overcome these limitations, we propose a novel three-stage segmentation framework that incorporates class-prior guidance and morphology-aware refinement. In the first stage, a 3D morphological constraint graph network (MCG-Net) is introduced, integrating a class prior constraint graph module (CPCGM) to dynamically model inter-class dependencies based on spatial and developmental priors of mixed dentition, and a morphological constraint module (MCM) to enhance structural precision through boundary-aware supervision. In the second stage, a 3D segmentation and classification refinement network (SCR-Net) is developed to jointly refine single-tooth segmentation and adjust the first-stage class predictions via multi-task learning, thereby mitigating the effects of tooth crowding and morphological variability. In the final stage, a class-weighted strategy based on voxel count is designed to reduce class conflicts in overlapping regions, improving segmentation accuracy for smaller teeth. The proposed framework is validated on a self-constructed mixed dentition dataset and a publicly available permanent dentition dataset. Quantitative and qualitative results demonstrate that our method achieves superior segmentation accuracy and robustness for mixed dentition, while maintaining competitive performance on permanent dentition. © 2026 Elsevier B.V.

Toward a Rigorous Classification of Loss of Productivity Quantification Methods

Item Type Journal Article

Author T. Zhao

Abstract Lost productivity is a common cause of cost overrun on construction projects and often results in construction claims. There are several different loss of productivity quantification methods and variants of those methods. Due to lack of adequate classification, the use of these methods is not well disciplined. For example, the implementation of the measured mile method can vary significantly between analysts or projects. This paper proposes a more rigorous classification system for loss of productivity quantification methods. This work first defines key dimensions of the hierarchy/matrix of the classification system, including productivity type, measurement perspective, data reliance, similarity requirement, analysis technique, work composition and divisions, causation, and others, and then places various loss of productivity quantification method implementations to different positions in the classification system. With this rigorous classification of loss of productivity methods, the variations between different method implementations can be clearly identified and the exact methodology can be applied to a construction claim in a well-defined and unambiguous manner. © 2025 American Society of Civil Engineers.

Toward Robust Semi-Supervised Distribution Alignment Against Label Distribution Shift With Noisy Annotations

Item Type Journal Article

Author B. Chen

Author Z. Ye

Author Y. Liu

Author X. Fang

Author G. Lu

Author S. Xie

Author X. Li

Abstract Deep learning-based AI models typically require a large amount of high-quality annotated data to achieve optimal performance. However, the label distribution shift caused by noisy annotations can lead to perturbations in the classification boundary, reducing the robustness and generalization capabilities of deep learning models. To mitigate this issue, we transform the problem of learning from noisy labels into a semi-supervised learning problem, and propose a novel Semi-Supervised Distribution Alignment (SSDA) framework that strategically integrates noise-robust distribution alignment within a unified semi-supervised learning paradigm for combating noisy labels. By leveraging the similarity distribution between historical predictions, the proposed SSDA approach benefits from a flexible multi-historical regression modeling strategy, which aims to identify high-confidence samples/pairs and recalibrate the label shift through pseudo-labels. Furthermore, our approach employs

a comprehensive multi-granularity distribution adaptation strategy, incorporating both instance-wise and class-aware distribution alignment to quantitatively minimize semantic discrepancies across different mixed feature domains. In this way, our SSDA approach ultimately achieves more resilient and generalizable performance against label noise, even in the presence of substantial noise. Extensive experiments conducted on multiple simulated and real-world noisy benchmark datasets consistently demonstrate the superiority and effectiveness of our SSDA method compared to existing state-of-the-art baselines. © 1999-2012 IEEE.

Toward Robust Uncertainty Estimation with Random Activation Functions

Item Type Conference Paper

Author Y. Stoyanova

Author S. Ghandi
Author M. Tavakol
Editor Williams B.
Editor Chen Y.
Editor Neville J.

Abstract Deep neural networks are in the limelight of machine learning with their excellent performance in many data-driven applications. However, they can lead to inaccurate predictions when queried in out-of-distribution data points, which can have detrimental effects especially in sensitive domains, such as healthcare and transportation, where erroneous predictions can be very costly and/or dangerous. Subsequently, quantifying the uncertainty of the output of a neural network is often leveraged to evaluate the confidence of its predictions, and ensemble models have proved to be effective in measuring the uncertainty by utilizing the variance of predictions over a pool of models. In this paper, we propose a novel approach for uncertainty quantification via ensembles, called Random Activation Functions (RAFTs) Ensemble, that aims at improving the ensemble diversity toward a more robust estimation, by accommodating each neural network with a different (random) activation function. Extensive empirical study demonstrates that RAFTs Ensemble outperforms state-of-the-art ensemble uncertainty quantification methods on both synthetic and real-world datasets in a series of regression tasks. Toward the classification of social media use disorder: Clinical characterization and proposed diagnostic criteria

Item Type Journal Article

Author T. Moretta

Author E. Wegmann

Abstract Empirical studies and theoretical models highlight that problematic use of social media can lead to significant functional impairments in several domains, such as social, relational, occupational, and psychological functioning, as well as physical health. However, social media use disorder is not currently recognized as an official disorder in major diagnostic systems, limiting comparability among studies, precise prevalence estimation, and ad-hoc preventive and treatment program development. The present work aims to classify social media use disorder as a pathological condition sharing main mechanisms and maladaptive patterns with addictive behaviors. We discuss diagnostic criteria for social media use disorder by integrating peculiar features of this maladaptive behavior with criteria for substance use disorders and behavioral addictions from major diagnostic systems (i.e., DSM-5 and ICD-11). Moreover, we address some controversies related to the classification of social media use disorder as a behavioral addiction and highlight literature findings indicating social media use disorder shares main alterations in mechanisms and processes characterizing addiction (i.e., maladaptive activation of reward systems and impairment of inhibitory control mechanisms). Despite the lack of studies including clinical populations and the need for future research to validate the proposed criteria and refine knowledge of the mechanisms underlying this condition, our work provides a structured framework for classifying and identifying social media use disorder. © 2025 The Author(s)

Towards a classification of holographic multi-partite entanglement measures

Item Type Journal Article

Author A. Gadde

Author V. Krishna

Author T. Sharma

Abstract In this paper, we systematically study the measures of multi-partite entanglement with the aim of constructing those measures that can be computed in probe approximation in the holographic dual. We classify and count general measures as invariants of local unitary transformations. After formulating these measures in terms of permutation group elements, we derive conditions that a probe measure should satisfy and find a large class of solutions. These solutions are generalizations of the multi-entropy introduced in [1]. We derive their holographic dual with the assumption that the replica symmetry is unbroken in the bulk and check our prescription with explicit computations in 2d CFTs. Analogous to the multi-entropy, the holographic dual of these measures is given by the weighted area of the minimal brane-web but with branes having differing tensions. We discuss the replica symmetry assumption and also how the already known entanglement measures, such as entanglement negativity and reflected entropy fit in our framework. © 2023, The Author(s).

Author Y. Zhang

Abstract Extensive investigation of microplastic abundance in soil environment calls for rapid, accurate, efficient and harmonized quantification methods. Development of rapid quantification method requires made-to-measure soil samples with additions of standard polymers. Existing rapid quantification methods ignore the gap between standard polymers in laboratory and household microplastics in soil environment. Here, terahertz (0.6–1.67 thz) and NIR (950–1660 nm) spectroscopy were compared to explore a fast, accurate and potentially generalizable microplastic quantification method in soil. Soil sample was spiked with two standard polymers (polyvinyl chloride (PVC) and polystyrene (PS)) and their additive-containing household microplastics. Two standard sample sets and two household sample sets were prepared in concentrations ranging from 0.5 to 10%. Nine commonly used preprocessing methods and three machine learning algorithms were coupled to develop methods. Models were constructed by training sets from standard sample sets. When models transferred to household samples, prediction error (RMSE) of proposed terahertz method (Wdenosie_PLSR) only increased by 0.4% for PVC and 0.19% for PS, yet that of the NIR method increased by 1.49% and 1.16% respectively. The proposed terahertz method presented a detection limit around 1.12% and the NIR method showed a detection limit around 3.24%. Overall, our results suggest that compared with NIR method, the proposed terahertz method is not only more accurate but also demonstrate stronger generalizability to bridge the gaps between standard PVC/PS polymers and household PVC/PS microplastics. We also

propose MMD heatmap for diagnosing spectral preprocessing methods to further improve method efficiency. © 2022 Elsevier B.V.

Towards a New Understanding of the Training of Neural Networks with Mislabeled Training Data

Item Type Conference Paper

Author H. Gish

Author J. Silovsky

Author M.-L. Sung

Author M.-H. Siu

Author W. Hartmann

Author Z. Jiang

Abstract We investigate the problem of machine learning with mislabeled training data. We try to make the effects of mislabeled training better understood through analysis of the basic model and equations that characterize the problem. This includes results about the ability of the noisy model to make the same decisions as the clean model and the effects of noise on model performance. In addition to providing better insights we also are able to show that the Maximum Likelihood (ML) estimate of the parameters of the noisy model determine those of the clean model. This property is obtained through the use of the ML invariance property and leads to an approach to developing a classifier when training has been mislabeled: namely train the classifier on noisy data and adjust the decision threshold based on the noise levels and/or class priors. We show how our approach to mislabeled training works with multi-layered perceptrons (MLPs). © 2020 IEEE.

Towards adaptive unknown authentication for universal domain adaptation by classifier paradox

Item Type Journal Article

Author Y. Wang

Author Y. Liu

Author S. Chen

Abstract Universal domain adaptation (UniDA) is a general unsupervised domain adaptation setting, which addresses both domain and label shifts in adaptation. Its main challenge lies in how to identify target samples in unshared or unknown classes. Previous methods commonly strive to depict sample “confidence” along with a threshold for rejecting unknowns, and align feature distributions of shared classes across domains. However, it is still hard to pre-specify a “confidence” criterion and threshold which are adaptive to different tasks, and a mis-prediction of unknowns further incurs mis-alignment of features in shared classes. In this paper, we propose a new UniDA method with adaptive Unknown Authentication by Classifier Paradox (UACP), considering that samples with paradoxical predictions are probably unknowns belonging to none of the source classes. In UACP, a composite classifier is jointly designed with two types of predictors. That is, a multi-class (MC) predictor classifies samples to one of the multiple source classes, while a binary one-vs-all predictor further verifies the prediction by MC predictor. Samples with verification failure or paradox are identified as unknowns. Further, instead of feature alignment for shared classes, implicit domain alignment is conducted in output space such that samples across domains share the same decision boundary, though with feature discrepancy. Empirical results validate UACP under both open-set and universal UDA settings. © The Author(s), under exclusive licence to Springer Science+Business Media LLC, part of Springer Nature 2022. Towards explainable spoofed speech attribution and detection: A probabilistic approach for characterizing speech synthesizer components

Item Type Journal Article**Author** J. Mishra**Author** M. Chhibber**Author** H.-J. Shim**Author** T.H. Kinnunen

Abstract We propose an explainable probabilistic framework for characterizing spoofed speech by decomposing it into probabilistic attribute embeddings. Unlike raw high-dimensional countermeasure embeddings, which lack interpretability, the proposed probabilistic attribute embeddings aim to detect specific speech synthesizer components, represented through high-level attributes and their corresponding values. We use these probabilistic embeddings with four classifier back-ends to address two downstream tasks: spoofing detection and spoofing attack attribution. The former is the well-known bonafide-spoof detection task, whereas the latter seeks to identify the source method (generator) of a spoofed utterance. We additionally use Shapley values, a widely used technique in machine learning, to quantify the relative contribution of each attribute value to the decision-making process in each task. Results on the ASVspoof2019 dataset demonstrate the substantial role of waveform generator, conversion model outputs, and inputs in spoofing detection; and inputs, speaker, and duration modeling in spoofing attack attribution. In the detection task, the probabilistic attribute embeddings achieve 99.7% balanced accuracy and 0.22% equal error rate (EER), closely matching the performance of raw embeddings (99.9% balanced accuracy and 0.22% EER). Similarly, in the attribution task, our embeddings achieve 90.23% balanced accuracy and 2.07% EER, compared to 90.16% and 2.11% with raw embeddings. These results demonstrate that the proposed framework is both

inherently explainable by design and capable of achieving performance comparable to raw CM embeddings. © 2025 The Authors

Towards invariant and interpretable representations for domain generalization in time series classification

Item Type Journal Article

Author Y. Chen

Author Z. Weng

Author B.H. Gwee

Author Q. Cao

Author S.G. Razul

Author Z. Lin

Abstract Time series classification is crucial in many real-world applications, but models often suffer significant performance degradation under domain shifts between training and testing data. Existing Domain Generalization (DG) methods for time series mainly suppress domain-specific information via adversarial training, but they remain

insufficient to obtain category-consistent representations. To address these challenges, we propose Joint Inference for Time Series Representation (JITSR), a variationally motivated novel framework for domain-generalized time series classification. Through joint variational modeling of time series and labels, JITSR connects patch reconstruction, categorical prediction, and distributional alignment as complementary learning objectives. The alignment term encourages category-consistent representations across domains without requiring explicit domain annotations. Specifically, JITSR segments time series into patches and maps them to latent distributions, which are quantized by a learnable distributional codebook. A dual-path alignment mechanism then aligns sample-level semantic distributions with codebook-level class priors. Meanwhile, attention-based codeword weighting identifies the temporal patterns that contribute to classification, providing interpretable evidence for the learned representations. Extensive experiments on diverse time series datasets demonstrate that JITSR consistently outperforms state-of-the-art DG methods and learns more category-consistent representations across domains. © 2026 Elsevier Ltd

Abstract Identifying IoT devices and managing their behaviors by analyzing network traffic is crucial to improving observability and security in modern network operations. Extensive prior research has focused on training machine learning models that identify IoT devices based on their network traffic collected at various granularities and vantage points. However, an under-explored challenge is the operational robustness of these models to shifts in class prevalence during inference, which is an inevitable consequence of the dynamic nature of IoT communications. By analyzing 640,000 IPFIX flow records collected from 12 real households, this paper makes three specific contributions. (1) We demonstrate that the distribution of IoT classes changes significantly over time in flow traces, matching the drop in classification performance. (2) By applying a Bayesian adjustment to the model's output scores using weights provided by an oracle, we recover many misclassified predictions, which also provides evidence for the hypothesis that the observed performance drop has been caused by the label shift. (3) As a practical alternative to the oracle, we explore the use of quantification methods to estimate class distributions in unlabeled data and show that they can successfully help adapt traffic classifiers to label shifts. © 2025 Copyright is held by the owner/author(s). Towards robust adversarial defense on perturbed graphs with noisy labels

Author Y. Du

Author X. Feng

Abstract Graph Neural Networks (GNNs) demonstrate powerful capabilities in graph representation learning tasks. However, real-world graphs are often perturbed and come with noisy labels, resulting in poor performance of GNNs in this scenario. To bridge this gap, we study a novel problem of developing robust graph adversarial defense on perturbed graphs with noisy labels, and propose a graph adversarial defense named Comprehensive Adversarial Defense (CARD). Initially, we utilize unsupervised singular value decomposition to separate the graph, preserving its main portion while isolating the mixed effects of perturbed graphs and noisy labels. Next, we employ an edge repairer to further restore the graph, thereby enhancing the robustness of GNNs against perturbed graphs. Subsequently, we perform fine-grained dynamic weighting of node-level losses during the training phase to prevent overfitting, and employ label alignment to address the significant label shift issue, thereby reducing the impact of noisy labels. Ultimately, we organize sufficient experiments under four benchmark datasets, four types of perturbed graphs, and two types of noisy labels. The empirical results validate the superior performance of CARD on the above adversarial scenarios. © 2025 Elsevier Ltd

Abstract As a major driver of global production, household consumption warrants increased attention due to its potential for decarbonization. This study systematically reviews 4647 journal papers to uncover evolving research themes and regional disparities in household carbon emissions research. We identified a marked increase in publications after 2015 and, using natural language processing, defined 7 distinct research clusters. While earlier studies focused primarily on energy consumption, more recent research has broadened to encompass a range of topics, including food systems, supply-chain emissions, and renewable energy. Our regional analysis reveals varied levels of research engagement across countries. The Global South is increasingly involved,

focusing on cooking facilities and household energy use, whereas Europe emphasizes policy-oriented mitigation. North America, led by the United States, focuses on transportation emissions and residential energy-efficiency modeling, while Asian countries examine urban-rural disparities and household inequality. Drawing on these thematic and geographical insights, this study identifies current knowledge gaps, such as the need for cross-regional comparisons and supply chain integration. These insights offer actionable directions to promote sustainable consumption practices and support global climate goals. © 2025

Traffic class prioritization-based slotted-CSMA/CA for IEEE 802.15.4 MAC in intra-WBANs

Item Type Journal Article

Author F. Masud

Author A.H. Abdullah

Author A. Altameem

Author G. Abdul-Salaam

Author F. Muchtar

Abstract This paper proposes an improved Traffic Class Prioritization based Carrier Sense Multiple Access/Collision Avoidance (TCP-CSMA/CA) scheme for prioritized channel access to heterogeneous-natured Bio-Medical Sensor Nodes (BMSNs) for IEEE 802.15.4 Medium Access Control (MAC) in intra-Wireless Body Area Networks (WBANs). The main advantage of the scheme is to provide prioritized channel access to heterogeneous-natured BMSNs of different traffic classes with reduced packet delivery delay, packet loss, and energy consumption, and improved throughput and packet delivery ratio (PDR). The prioritized channel access is achieved by assigning a distinct, minimized and prioritized backoff period range to each traffic class in every backoff during contention. In TCP-CSMA/CA, the BMSNs are distributed among four traffic classes based on the existing patient's data classification. The Backoff Exponent (BE) starts from 1 to remove the repetition of the backoff period range in the third, fourth, and fifth backoffs. Five moderately designed backoff period ranges are proposed to assign a distinct, minimized, and prioritized backoff period range to each traffic class in every backoff during contention. A comprehensive verification using NS-2 was carried out to determine the performance of the TCP-CSMA/CA in terms of packet delivery delay, throughput, PDR, packet loss ratio (PLR) and energy consumption. The results prove that the proposed TCP-CSMA/CA scheme performs better than the IEEE 802.15.4 based PLA-MAC, eMC-MAC, and PG-MAC as it achieves a 47% decrease in the packet delivery delay and a 63% increase in the PDR. © 2019 by the authors. Editor House D.

Abstract In current HMM/DNN speech recognition systems, the purpose of the DNN component is to estimate the posterior probabilities of tied triphone states. In most cases the distribution of these states is uneven, meaning that we have a markedly different number of training samples for the various states. This imbalance of the training data is a source of suboptimality for most machine learning algorithms, and DNNs are no exception. A straightforward solution is to re-sample the data, either by upsampling the rarer classes or by downsampling the more common classes. Here, we experiment with the so-called probabilistic sampling method that applies downsampling and up-sampling at the same time. For this, it defines a new class distribution for the training data, which is a linear combination of the original and the uniform class distributions. As an extension to previous studies, we propose a new method to re-estimate the class priors, which is required to remedy the mismatch between the training and the test data distributions introduced by re-sampling. Using probabilistic sampling and the proposed modification we report 5% and 6% relative error rate reductions on the TED-LIUM and on the AMI corpora, respectively. Copyright © 2017 ISCA.

Transductive Few-Shot Learning With High-Order Representation for Cross-Domain Hyperspectral Image Classification

Item Type Journal Article

Author H. Pan

Author R. Zhao

Author C. Shi

Author H. Ge

Author Y. Jin

Author M. Liu

Abstract Cross-domain hyperspectral image classification (HSIC) under few-shot conditions remains a formidable challenge due to severe data scarcity and pronounced cross-domain discrepancies. Recent advances in transductive few-shot learning (TFSL) offer a promising paradigm for tackling this problem. However, effective feature encoding, which is fundamental to TFSL, remains challenging for HSIs due to their complex high-order spectral-spatial correlations. Moreover, most existing TFSL methods assume a uniform class prior over query samples, which introduces severe bias under domain distribution mismatch and class imbalance, leading to significant performance degradation. To this end, we propose a novel method termed TFSL with high-order transformer-few shot learning (HOT-FSL), which mainly consists of three key components: high-order transformer encoder (HOTE), prototype-conditioned gated interaction module (PCGI), and conditional transport-based prototype-oriented unbiased transfer (CTPUT). The proposed HOTE employs factorized high-order attention with Kronecker-structured formulations to jointly model spatial-spectral dependencies and long-range interactions in HSI. PCGI models class prototypes from the support set and adaptively injects them into query features via contrastive routing,

thereby enhancing feature discriminability and class consistency. During inference, CTPUT employs conditional transport (CT) with forward-backward navigators and an expectation-maximization (EM)-based solver to iteratively learn unbiased class statistics and refine prototypes under imbalanced query distributions. Comprehensive experimental results on three widely used benchmarks consistently validate the superior performance of the proposed method. Transductive methods for distributed ensemble classification

Item Type Conference Paper

Author D.J. Miller

Author S. Pal

Abstract We consider ensemble classification for the case when there is no common labeled training data for designing the function which aggregates individual classifier decisions. We dub this problem distributed ensemble classification, addressing e.g. when individual classifiers are trained on different (e.g. proprietary, legacy) databases or operate (perhaps remotely) on different sensing modalities. Typically, fixed, principled (untrained) rules of classifier combination such as voting methods are used in this case for aggregating decisions. Alternatively, we take a transductive approach, optimizing the combining rule for an objective function measured on the unlabeled batch of test data. We propose specific maximum likelihood (ML) objectives that are shown to yield well-known forms of aggregation, albeit with iterative, EM-based adjustment to account for possible mismatch between the class priors used by individual classifiers and those reflected in the new data batch. We also propose an information-theoretic method which outperforms the ML methods and addresses some problem instances where the ML methods are not applicable. On benchmark data from the UC Irvine machine learning repository, all our methods give improvements in accuracy over the use of fixed rules when there is prior mismatch. © 2006 IEEE.

Transductive methods for the distributed ensemble classification problem

Item Type Journal Article

Author D.J. Miller

Author S. Pal

Abstract We consider ensemble classification for the case where there is no common labeled training data for jointly designing the individual classifiers and the function that aggregates their decisions. This problem, which we call distributed ensemble classification, applies when individual classifiers operate (perhaps remotely) on different sensing modalities and when combining proprietary or legacy classifiers. The conventional wisdom in this case is to apply fixed rules of combination such as voting methods or rules for aggregating probabilities. Alternatively, we take a transductive approach, optimizing the combining rule for an objective function measured on the unlabeled batch of test data. We propose maximum likelihood (ML) objectives that are shown to yield well-known forms of probabilistic aggregation, albeit with iterative, expectation-maximization-based adjustment to account for mismatch between class priors used by individual classifiers and those reflected in the new data batch. These methods are extensions, for the ensemble case, of the work of Saerens, Latinne, and Decaestecker (2002). We also propose an information-theoretic method that generally outperforms the ML methods, better handles classifier redundancies, and addresses some scenarios where the ML methods are not applicable. This method also well handles the case of missing classes in the test batch. On UC Irvine benchmark data, all our methods give improvements in classification accuracy over the use of fixed rules when there is prior mismatch. © 2007 Massachusetts Institute of Technology.

Abstract Transductive learning is a supervised machine learning task in which, unlike in traditional inductive learning, the unlabelled data that require labelling are a finite set and are available at training time. Similarly to inductive learning contexts, transductive learning contexts may be affected by dataset shift, i.e., may be such that the assumption according to which the training data and the unlabelled data are independently and identically distributed (IID), does not hold. We here propose a method, tailored to transductive classification contexts, for performing model selection (i.e., hyperparameter optimisation) when the data exhibit prior probability shift, an important type of dataset shift typical of anti-causal learning problems. In our proposed method the hyperparameters can be optimised directly on the unlabelled data to which the trained classifier must be applied; this is unlike traditional model selection methods, that are based on performing cross-validation on the labelled training data. By tailoring model selection to the actual test distribution, our approach contributes to the trustworthiness of AI systems, as it enables more reliable and robust classifier deployment under changed conditions. We provide experimental results that show the benefits brought about by our method. © 2025 Copyright for this paper by its authors.

Transfer estimation and the applications in data stream classification

Item Type Conference Paper

Author Z. Zhang

Author J. Zhou

Abstract Transfer estimation is a new parameter estimation method, which utilizes samples from not only the target distribution but also related ones. It is based on traditional estimators and can be used to solve the problem of small sample estimation. The key problem in transfer estimation is how to set the weighting coefficients when designing the transfer estimators. In this paper, we will propose a new algorithm to solve this problem. First, we will propose a common rule. Following the proposed rule, we can formulate the weighting coefficient setting problem as a constrained optimization problem. We will introduce an alternating optimized method and get a new algorithm of transfer estimation. The estimation of evolving class priors in data stream classification is a typical and important small sample estimation problem. In this paper, we will apply the proposed transfer estimation algorithm to the class prior estimation. Experiments on benchmark data sets will be performed, which show that the proposed algorithm can improve the performance on both class prior estimation and the final data stream classification. © 2011 SPIE.

Transfer estimation of evolving class priors in data stream classification

Item Type Journal Article**Author** Z. Zhang**Author** J. Zhou

Abstract Data stream classification is a hot topic in data mining research. The great challenge is that the class priors may evolve along the data sequence. Algorithms have been proposed to estimate the dynamic class priors and adjust the classifier accordingly. However, the existing algorithms do not perform well on prior estimation due to the lack of samples from the target distribution. Sample size has great effects in parameter estimation and small-sample effects greatly contaminate the estimation performance. In this paper, we propose a novel parameter estimation method called transfer estimation. Transfer estimation makes use of samples not only from the target distribution but also from similar distributions. We apply this new estimation method to the existing algorithms and obtain an improved algorithm. Experiments on both synthetic and real data sets show that the improved algorithm outperforms the existing algorithms on both class prior estimation and classification. © 2010 Elsevier Ltd. Transfer Learning in Astronomy: A New Machine-Learning Paradigm

Item Type Conference Paper

Author R. Vilalta

Abstract The widespread dissemination of machine learning tools in science, particularly in astronomy, has revealed the limitation of working with simple single-task scenarios in which any task in need of a predictive model is looked in isolation, and ignores the existence of other similar tasks. In contrast, a new generation of techniques is emerging where predictive models can take advantage of previous experience to leverage information from similar tasks. The new emerging area is referred to as transfer learning. In this paper, I briefly describe the motivation behind the use of transfer learning techniques, and explain how such techniques can be used to solve popular problems in astronomy. As an example, a prevalent problem in astronomy is to estimate the class of an object (e.g., Supernova Ia) using a generation of photometric light-curve datasets where data abounds, but class labels are scarce; such analysis can benefit from spectroscopic data where class labels are known with high confidence, but the data sample is small. Transfer learning provides a robust and practical solution to leverage information from one domain to improve the accuracy of a model built on a different domain.

In the example above, transfer learning would look to overcome the difficulty in the compatibility of models between spectroscopic data and photometric data, since data properties such as size, class priors, and underlying distributions, are all expected to be significantly different. © Published under licence by IOP Publishing Ltd.

Transfer Learning-Based UAV Swarm Threat Perception and Evaluation Scheme in Air-Ground-Integrated Networks

Item Type Conference Paper

Author Y. Hou

Author S. Liu

Author L. Zhou

Author R. Zhang

Author Q. Shi

Abstract With the advancement of 5G and artificial intelligence technologies, unmanned aerial vehicle (UAV) has emerged as crucial elements in modern warfare. However, their small size and slow speed make them difficult to detect and easily mistaken for birds or other flying objects, posing challenges for defenders to respond promptly. Moreover, existing methods for evaluating UAV threats heavily rely on subjective expert scoring, leading to inefficiency, uncertainty, and ambiguity. In this paper, we propose a comprehensive approach for UAV swarm threat perception and evaluation in integrated air-ground networks. By integrating historical observation data, we establish an indicator quantification method to evaluate the perception of UAV swarm threats. Initially, we employ convolutional neural networks for intent recognition, allowing for coarse-grained classification of enemy UAVs. Subsequently, we utilize transfer learning to in-corporate the trained intent recognition model into the threat evaluation framework, significantly enhancing the efficiency and accuracy of UAV threat evaluation. Experimental results confirm the superior performance of our UAV swarm threat perception and evaluation model compared to existing approaches. © 2023 IEEE.

Transmission biology of Raspberry latent virus, the first aphid-borne reovirus

Item Type Journal Article

Author D.F. Quito-Avila

Author D. Lightle

Author J. Lee

Author R.R. Martin

Abstract Raspberry latent virus (RpLV) is a newly characterized reovirus found in commercial raspberry fields in the Pacific Northwest (PNW). Thus far, all members of the plant reoviruses are transmitted in a replicative, persistent manner by several species of leafhoppers or planthoppers. After several failed attempts to transmit RpLV using leafhoppers, the large raspberry aphid, commonly found in the PNW, was tested as a vector of the virus. The virus was transmitted to new, healthy raspberry plants when inoculated with groups of at least 50 viruliferous aphids, suggesting that aphids are vectors of RpLV, albeit inefficient ones. Using absolute and relative quantification methods, it was shown that the virus titer in aphids continued to increase after the acquisition period even when aphids were serially transferred onto fresh, healthy plants on a daily basis. Transmission experiments determined that RpLV has a 6-day latent period in the aphid before it becomes transmissible; however, it was not transmitted transovarially to the next generation. To our knowledge, this is the first report of a plant reovirus transmitted by an aphid. Phylogenetic analyses showed that RpLV is related most closely to but distinct from Rice ragged stunt virus (RRSV), the type member of the genus Oryzavirus. Moreover, the conserved nucleotide termini of the genomic segments of RpLV did not match those of RRSV or other plant reoviruses, allowing us to suggest that RpLV is probably the type member of a new genus in the Reoviridae comprising aphid-transmitted reoviruses. © 2012 The American Phytopathological Society.

TRAPL: Transformer-Based Patch Learning for Enhancing Semantic Representations Using Aggregated Features to Estimate Patch-Class Distribution

Item Type Conference Paper

Author S.R. Jyhne

Author P.-A. Andersen

Author I. Oveland

Author M. Goodwin

Editor Bramer M.

Editor Stahl F.

Abstract We introduce TRAPL, a Transformer-based Patch Learning technique that enhances semantic representations in segmentation models. TRAPL leverages aggregated features for precise patch-class distribution estimation, gathering features at key layers in the Transformer architecture. The method integrates an auxiliary objective with a convolution-based classifier, enabling robust semantic learning at the patch level. Our experiments demonstrate significant improvements in Intersection-over-Union (IoU) performance across models and datasets. TRAPL is compatible with both flat and hierarchical Transformers, ensuring minimal computational load during training and no extra overhead during inference. Our evaluations across state-of-the-art models and benchmarks demonstrate TRAPL's effectiveness for improving Transformer-based semantic segmentation. © The Author(s), under exclusive license to Springer Nature Switzerland AG 2025.

Tree-driven optimization inference strategy for highly resource-demanding data acquisition: Application to chemical sensors

Item Type Conference Paper

Author M. Pavone

Author R. Alesii

Author S. Tennina

Author G. Pola

Abstract Radio-frequency-based chemical sensors are a promising approach for noninvasive, low-cost identification of substances across a wide range of applications, including medical and biological contexts. However, their practical deployment is often limited by high costs or long acquisition times required to collect high-resolution spectral features, which adversely affect energy consumption, responsiveness, and the ability to capture fast-evolving chemical phenomena in healthcare applications. In this work, we address this limitation by proposing an acquisition-aware classification framework that exploits the intrinsic sequential structure of tree-based learning algorithms. Building on a previously introduced wireless chemical-sensing platform based on spectral analysis, we investigate the combined use of feature selection and decision-tree-based inference to reduce both data acquisition and inference costs. The proposed

approach models the sensing process as a query-driven system in which radio-frequency features are acquired conditionally as a classification tree is traversed. As a result, the number of acquired features required for inference is bounded by the depth of the tree rather than by the dimensionality of the full feature space. On a preliminary dataset spanning 3-6 GHz (1000 candidate features) and multiple substances, our results indicate that accurate classification can be achieved with a small subset of features, yielding a substantial reduction of expected acquisition/inference time in balanced operating conditions (>30%), with further gains when class priors are available. Furthermore, the proposed inference strategy allows additional savings when prior knowledge about class occurrence probabilities is available. These findings highlight the potential of acquisition-aware, tree-based models as an effective solution for real-world radio-frequency chemical sensing systems operating under strict time and energy constraints. © 2026 IEEE.

Author W.-S. Su

Abstract Objective: To investigate the academic use of artificial intelligence (AI) in nursing. Background: A bibliometric analysis combined with the VOSviewer software quantification method has been utilized for a literature analysis. In recent years, this approach has attracted the interest of scholars in various research fields. Thus far, there is no publication using bibliometric analysis combined with the VOSviewer software to analyse the applications of AI in nursing. Method: A bibliometric analysis methodology was used to search for relevant articles published between 1984 and March 2022. Six databases, Embase, Scopus, PubMed, CINAHL, WoS and MEDLINE, were included to identify relevant studies, and data such as the year of publication, journals, country, institutional source, field and keywords were analysed. Results: Most relevant articles were published from institutions in the United States. The League of European Research Universities has published most research studies that use AI and nursing. Scholars have mainly focused on nursing, medical informatics, computer science AI, healthcare sciences services and physics particles fields. Commonly used keywords were machine learning, care, AI, natural language processing, prediction and nurse. Conclusion: Research articles were mainly published in Nurse Education Today. Research topics such as AI-assisted medical recording and medical decision making were also identified. According to this study, AI in nursing has the potential to attract more attention from researchers and nursing managers. Additional high-quality research beyond the scope of medical education, as well as on cross-domain collaboration, is warranted to explore the acceptability and effective implementation of AI technologies. Implications for Nursing Management: This study provides scholars and nursing managers with structured information regarding the use of AI in nursing based on scientific and technological developments across different fields and institutions. The application of AI can improve nursing management, nursing quality, safety management and team communication, as well as encourage future international collaboration. © 2022 John Wiley & Sons Ltd.

Trends in concept and nosology of autism spectrum disorder: A review

Item Type Journal Article

Author S. Gyawali

Author B.N. Patra

Abstract Autism Spectrum Disorder is a neurodevelopmental disorder characterized by persistent deficits in social communication, social interaction and restricted, repetitive patterns of behavior, interests or activities. The concept of autism has changed since its inception, from childhood schizophrenia to neuro-variation. These changes in concept have been accompanied by changes in the diagnostic threshold through which the 'case' of autism is identified. The occurrence of multiple changes in its diagnostic criteria over last 80 odd years opens up the possibility of challenges being posed to the existence of the disorder as it is today, with a possibility of newer conceptualization of autism coming up in the future. The potential consequences of the changes in its nosology and concept, such as those on the management and on prevalence estimation are some of the essential issues which need attention. In the current paper, we evaluate the evolution of the concept and nosology of autism with an overview of the accompanying impact of these changes. © 2019 Elsevier B.V.

TriDroid: a triage and classification framework for fast detection of mobile threats in android markets

Item Type Journal Article

Author A. Amira

Author A. Derhab

Author E.M.B. Karbab

Author O. Nouali

Author F.A. Khan

Abstract The Android platform is highly targeted by malware developers, which aim to infect the maximum number of mobile devices by uploading their malicious applications to different app markets. In order to keep a healthy Android ecosystem, app-markets check the maliciousness of newly submitted apps. These markets need to (a) correctly detect malicious app, and (b) speed up the detection process of the most likely dangerous applications among an overwhelming flow of submitted apps, to quickly mitigate their potential damages. To address these challenges, we propose TriDroid, a market-scale triage and classification system for Android apps. TriDroid prioritizes apps analysis according to their risk likelihood. To this end, we categorize the submitted apps as: botnet, general malware, and benign. TriDroid starts by performing a (1) Triage process, which applies a fast coarse-grained and less-accurate analysis on a continuous stream of the submitted apps to identify their corresponding queue in a three-class priority queuing system. Then, (2) the Classification process extracts fine-grained static features from the apps in the priority queue, and applies three-class machine learning classifiers to confirm with high accuracy the classification decisions of the triage process. In addition to the priority queuing model, we also propose a multi-server queuing model where the classification of each app category is run on a different server. Experiments on a dataset with more than 24K malicious and 3K benign applications show that the priority model offers a trade-off between waiting time and processing overhead, as it requires only one server compared to the multi-server model. Also it successfully prioritizes malicious apps analysis, which allows a short waiting time for dangerous applications compared to the FIFO policy. © 2020, Springer-Verlag GmbH Germany, part of Springer Nature.

Abstract The increasing adoption of machine learning and deep learning models in critical applications raises the issue of ensuring their trustworthiness, which can be addressed by quantifying the uncertainty of their predictions. However, the black-box nature of many such models allows only to quantify uncertainty through ad hoc superstructures, which require to develop and train a model in an uncertainty-aware fashion. However, for applications where previously trained models are already in operation, it would be interesting to develop uncertainty quantification approaches acting as lightweight “plug-ins” that can be applied on top of such models without modifying and re-training them. In this contribution we present a research activity of the Pattern Recognition and Applications Lab of the University of Cagliari related to a recently proposed post hoc uncertainty quantification method, we named dropout injection, which is a variant of the well-known Monte Carlo dropout, and does not require any re-training nor any further gradient descent-based optimization; this makes it a promising, lightweight solution for integrating uncertainty quantification on any already-trained neural network. We are investigating a theoretically grounded solution to make dropout injection as effective as Monte Carlo dropout through a suitable rescaling of its uncertainty measure; we are also evaluating its effectiveness in the computer vision tasks of crowd counting and density estimation for intelligent video surveillance, thanks to our participation in a project funded by the European Space Agency. © 2022 Copyright for this paper by its authors. Trustworthy clinical AI solutions: A unified review of uncertainty quantification in Deep Learning models for medical image analysis

Item Type Journal Article

Author B. Lambert

Author F. Forbes

Author S. Doyle

Author H. Dehaene

Author M. Dojat

Abstract The full acceptance of Deep Learning (DL) models in the clinical field is rather low with respect to the quantity of high-performing solutions reported in the literature. End users are particularly reluctant to rely on the opaque predictions of DL models. Uncertainty quantification methods have been proposed in the literature as a potential solution, to reduce the black-box effect of DL models and increase the interpretability and the acceptability of the result by the final user. In this review, we propose an overview of the existing methods to quantify uncertainty associated with DL predictions. We focus on applications to medical image analysis, which present specific challenges due to the high dimensionality of images and their variable quality, as well as constraints associated with real-world clinical routine. Moreover, we discuss the concept of structural uncertainty, a corpus of methods to facilitate the alignment of segmentation uncertainty estimates with clinical attention. We then discuss the evaluation protocols to validate the relevance of uncertainty estimates. Finally, we highlight the open challenges for uncertainty quantification in the medical field. © 2024 The Author(s)

Abstract The lack of a gold standard synergy quantification method for chemotherapeutic drug combinations warrants the consideration of different synergy metrics to develop efficient predictive models. Furthermore, neglecting combination sensitivity may lead to biased synergistic combinations, which are ineffective in cancer treatment. In this paper, we propose a deep learning-based model, SynPredict, which effectively predicts synergy in five synergy metrics together with the combination sensitivity score. SynPredict assesses the impact of multimodal fusion architectures of the input data, including the gene expression data of cancer cells, along with the representative chemical features of drugs in pairwise combinations. Both ONEIL and ALMANAC anticancer combination datasets are employed comparatively. The impact of the training datasets was more significant and consistent across most synergy models than input data fusion architectures. Synpredict outperforms the state-of-the-art predictive models, including DeepSynergy, AuDNN synergy, TranSynergy and DrugComb, with up to 74% decline in the mean square error. We highlight the pivotal need to consider a multiplex of synergy metrics and the combined sensitivity in the predictive models. © 2013 IEEE.

Trustworthy Open Set Domain Generalization Network for Unknown Fault Diagnosis Under Unseen Conditions

Item Type Journal Article

Author Z. Fan

Author B. Yan

Author C. Xu

Author S. Lu

Author K. Zhong

Abstract Advanced intelligent fault diagnosis (IFD) methods based on domain generalization (DG) leverage multisource sensor data to overcome the limitations the limitations of domain adaptation (DA)-based models regarding target data demand in the training stage, which resolves domain shift problems under unseen conditions in industrial instrumentation. However, previous studies primarily focused on the closed-set diagnosis with same label space shared by the training and testing data, which struggle to address the problem of new fault identification under intricate industrial dynamics. To overcome this obstacle, a trustworthy evidential open-set DG network (EOSDGN) is proposed for open-set fault diagnosis under unseen conditions. In the EOSDGN method, an evidential deep classifier is constructed to quantify the uncertainty of predicted results, an evidential domain discriminator is employed to integrate the data from diverse source domains, and an evidential uncertainty calibration is established to reconcile the misleading evidence and class-based evidence assignments. The EOSDGN model effectively addresses both domain and label shift challenges by integrating domain-invariant features extraction and uncertainty quantification of the predicted probabilities, which enables efficient classification of known faults while simultaneously facilitating the identification of unknown faults. The effectiveness of the EOSDGN model has been substantiated using public and practical datasets. Experimental findings demonstrate that the EOSDGN model surpasses the performance of the state-of-the-art models. © 1963-2012 IEEE.

Tunnel surrounding rock joint recognition and rock mass integrity evaluation based on an improved YOLOv8-seg model

Item Type Journal Article

Author W. Dong

Author W. Zou

Author L. Xu

Author Z. Ren

Abstract Rock fractures significantly influence rock classification and engineering parameter determination. Traditional joint extraction methods are time-consuming, subjective, and error-prone, hindering intelligent tunnel engineering and compromising construction safety. This study proposes an automated rock integrity quantification method using the GAM-BiFPN-YOLOv8-seg model. A standardized process for collecting tunnel face images was established, creating a diverse joint image dataset. Incorporating global attention mechanisms and weighted bidirectional feature pyramid networks into the YOLOv8-seg framework improved detection of subtle joint features and multi-scale fusion, enhancing joint extraction accuracy. After binarization and applying the Zhang-Suen thinning algorithm, joint traces were combined with surrounding joint counts to automate rock integrity quantification. Integrating the relationship between surrounding rock joint counts and rock mass integrity indices, the method achieved a 6.34% improvement in mAP50 and an 8.42% improvement in mAP50:95 compared to the original YOLOv8-seg network, with marginal gains in detection speed. During engineering validation at the NEOM New City Tunnel project, the proposed method demonstrated consistent performance with human decision-making in quantifying tunnel face joints. The method provides an effective solution for the accurate assessment of rock mass integrity and has broad

application prospects in the field of tunnel engineering and geological engineering. ©

Editor Christiansen H.

Abstract Quantification is the task of estimating, given a set of unlabelled items and a set of classes, the relative frequency (or “prevalence”). Quantification is important in many disciplines (such as e.g., market research, political science, the social

sciences, and epidemiology) which usually deal with aggregate (as opposed to individual) data. In these contexts, classifying individual unlabelled instances is usually not a primary goal, while estimating the prevalence of the classes of interest in the data is. Quantification may in principle be solved via classification, i.e., by classifying each item in and counting, for all, how many such items have been labelled with. However, it has been shown in a multitude of works that this “classify and count” (CC) method yields suboptimal quantification accuracy, one of the reasons being that most classifiers are optimized for classification accuracy, and not for quantification accuracy. As a result, quantification has come to be no longer considered a mere byproduct of classification, and has evolved as a task of its own, devoted to designing methods and algorithms that deliver better prevalence estimates than CC. The goal of this tutorial is to introduce the main supervised learning techniques that have been proposed for solving quantification, the metrics used to evaluate them, and the most promising directions for further research. © 2019, Springer Nature Switzerland AG.

Tweet sentiment quantification: An experimental re-evaluation

Item Type Journal Article**Author** A. Moreo**Author** F. Sebastiani

Abstract Sentiment quantification is the task of training, by means of supervised learning, estimators of the relative frequency (also called "prevalence") of sentiment-related classes (such as Positive, Neutral, Negative) in a sample of unlabelled texts. This task is especially important when these texts are tweets, since the final goal of most sentiment classification efforts carried out on Twitter data is actually quantification (and not the classification of individual tweets). It is well-known that solving quantification by means of "classify and count" (i.e., by classifying all unlabelled items by means of a standard classifier and counting the items that have been assigned to a given class) is less than optimal in terms of accuracy, and that more accurate quantification methods exist. Gao and Sebastiani 2016 carried out a systematic comparison of quantification methods on the task of tweet sentiment quantification. In hindsight, we observe that the experimentation carried out in that work was weak, and that the reliability of the conclusions that were drawn from the results is thus questionable. We here re-evaluate those quantification methods (plus a few more modern ones) on exactly the same datasets, this time following a now consolidated and robust experimental protocol (which also involves simulating the presence, in the test data, of class prevalence values very different from those of the training set). This experimental protocol (even without counting the newly added methods) involves a number of experiments 5,775 times larger than that of the original study. Due to the above-mentioned presence, in the test data, of samples characterised by class prevalence values very different from those of the training set, the results of our experiments are dramatically different from those obtained by Gao and Sebastiani, and provide a different, much more solid understanding of the relative strengths and weaknesses of different sentiment quantification methods. © 2022 Moreo, Sebastiani. Twise at SemEval-2017 Task 4: Five-point Twitter Sentiment Classification and Quantification

- Item Type** Conference Paper
- Author** G. Balikas
- Abstract** The paper describes the participation of the team “Twise” in the SemEval-2017 challenge. Specifically, I participated at Task 4 entitled “Sentiment Analysis in Twitter” for which I implemented systems for five-point tweet classification (Subtask C) and five-point tweet quantification (Subtask E) for English tweets. In the feature extraction steps the systems rely on the vector space model, morpho-syntactic analysis of the tweets and several sentiment lexicons. The classification step of Subtask C uses a Logistic Regression trained with the one-versus-rest approach. Another instance of Logistic Regression combined with the classify-and-count approach is trained for the quantification task of Subtask E. In the official leaderboard the system is ranked 5/15 in Subtask C and 2/12 in Subtask E. © 2017 Association for Computational Linguistics

Two-group classification via a biobjective margin maximization model

Item Type Journal Article**Author** E. Carrizosa**Author** B. Martin-Barragan

Abstract In this paper we propose a biobjective model for two-group classification via margin maximization, in which the margins in both classes are simultaneously maximized. The set of Pareto-optimal solutions is described, yielding a set of parallel hyperplanes, one of which is just the solution of the classical SVM approach. In order to take into account different misclassification costs or a priori probabilities, the ROC curve can be used to select one out of such hyperplanes by expressing the adequate tradeoff for sensitivity and specificity. Our result gives a theoretical motivation for using the ROC approach in case misclassification costs in the two groups are not necessarily equal. © 2005 Elsevier B.V. All rights reserved.

Two-phase sampling for simultaneous prevalence estimation and case detection

Item Type Journal Article

Author R. McNamee

Abstract Two-phase designs for estimation of prevalence, where the first-phase classification is fallible and the second is accurate but relatively expensive, are not necessarily justified on efficiency grounds. However, they might be advantageous for dual-purpose studies, for example where prevalence estimation is followed by a clinical trial or case-control study, if they can identify cases of disease for the second study in a cost-effective way. Alternatively, they may be justified on ethical grounds if they can identify more, previously undetected but treatable cases of disease, than a simple random sample design. An approach to sampling is proposed, which formally combines the goals of efficient prevalence estimation and case detection by setting different notional study costs for investigating cases and noncases. Two variants of the method are compared with an "ethical" two-phase scheme proposed by Shrout and Newman (1989, *Biometrics* 45, 549-555), and with the most efficient scheme for prevalence estimation alone, in terms of the standard error of the prevalence estimate, the expected number of cases, and the fraction of cases among second-phase subjects, given a fixed budget. One variant yields the highest fraction and expected number of cases but also the largest standard errors. The other yields a higher fraction than Shrout and Newman's scheme and a similar number of cases but appears to do so more efficiently.

U-TraCE: a conformal prediction approach to uncertainty quantification in black-box models

Item Type Journal Article

Author E. J Marchi

Author M. Liebl

Abstract Modern machine learning (ML) systems, particularly deep neural networks, have become increasingly complex and opaque, making reliable uncertainty quantification (UQ) essential. Conventional UQ methods often prove inadequate for black-box model evaluation scenarios, either because model internals are not accessible or because the resulting uncertainty is expressed in terms of a related predictor rather than the model under evaluation. We introduce U-TraCE (Uncertainty Tracking for Complex Estimators), a novel UQ method built on the Conformal Prediction (CP) framework that provides formal and traceable uncertainty bounds for opaque ML systems. Unlike existing CP approaches, which describe uncertainty through confidence intervals or prediction set sizes at a fixed uncertainty level, U-TraCE yields an explicit numerical bound on the error probability of the standalone black-box model. U-TraCE was evaluated on diverse tasks, including MNIST classification and cardiac magnetic resonance imaging (MRI) segmentation, representing both benchmark and real-world domains. Across these settings, it produced conservative yet well-calibrated uncertainty bounds that closely follow empirical uncertainty, even with limited calibration data. By bridging theoretical UQ and operational model validation, U-TraCE establishes a foundation for objective and automated conformity assessment of complex ML systems, supporting trustworthy deployment in safety-critical environments. © 2026 The Author(s). UGPL: Uncertainty-Guided Progressive Learning for Evidence-Based Classification in Computed Tomography

Item Type Conference Paper

Author S. Venkatraman

Author S. Pavan Kumar

Author R.R. Madavan

Author S. Chandrakala

Abstract Accurate classification of computed tomography (CT) images is essential for diagnosis and treatment planning, but existing methods often struggle with the subtle and spatially diverse nature of pathological features. Current approaches typically process images uniformly, limiting their ability to detect localized abnormalities that require focused analysis. We introduce UGPL, an uncertainty-guided progressive learning framework that performs a global-to-local analysis by first identifying regions of diagnostic ambiguity and then conducting detailed examination of these critical areas. Our approach employs evidential deep learning to quantify predictive uncertainty, guiding the extraction of informative patches through a non-maximum suppression mechanism that maintains spatial diversity. This progressive refinement strategy, combined with an adaptive fusion mechanism, enables UGPL to integrate both contextual information and fine-grained details. Experiments across three CT datasets demonstrate that UGPL consistently outperforms state-of-the-art methods, achieving improvements of 3.29%, 2.46%, and 8.08% in accuracy for kidney abnormality, lung cancer, and

COVID-19 detection, respectively. Our analysis shows that the uncertainty-guided component provides substantial benefits, with performance dramatically increasing when the full progressive learning pipeline is implemented. Our code is available at <https://github.com/shravan-18/UGPL>. © 2025 IEEE.

Ultra-Sensitive and Validated method for Trace Quantification of Carcinogenic Benzene in Cetirizine Dihydrochloride

- Item Type** Journal Article

Abstract Benzene (BENZ) is classified as a Class 1 residual solvent according to ICH Q3C guidelines due to its established classification as a Group 1 human carcinogen. During the chemical production of Cetirizine Dihydrochloride (CTZ) API, Cetirizine Dihydrochloride tablet (CTZT), Levocetirizine Dihydrochloride (LCTZ) API, and Levocetirizine Dihydrochloride tablet (LCTZT), BENZ can appear as a residual process impurity with carcinogenic risk; development of a highly sensitive quantification method is a critical requirement for pharmaceutical quality control. This study focused on developing and validating a method for detecting trace-level BENZ in CTZ and LCTZ drug substance and drug product. The method demonstrated exceptional sensitivity, with a least detectable concentration of 0.04 ppm and a quantifiable concentration of 0.12 ppm, significantly lower than the ICH-mandated safety limit of 2 ppm. Linearity and accuracy studies yielded an outstanding percentage of samples spiked BEN in the drug substance and drug product of CTZ and LCTZ and found within acceptance limit, approving the method's validity in presence of the drug atmosphere. Conventional headspace GC-FID/GC-MS are established techniques for benzene analysis; the proposed HPLC method offers a simpler, cost-effective, and validated method, making it well suited for routine quality control laboratories where GC facilities may not be readily available. © 2026 John Wiley & Sons Ltd.

Ultrasound Operator Variance Classification for Agency in Artificial Intelligence Support of Cyber-Physical Systems

Item Type Conference Paper

Author C. Zhu

Author T.E. Doyle

Author M.D. Noseworthy

Abstract Ultrasound (US) is the most widely used medical imaging modality due to its low cost, portability, real time imaging ability and use of non-ionizing radiation. However, unlike other imaging modalities such as CT or MRI, it is a heavily operator dependent, requiring trained expertise to leverage these benefits. More broadly, the natural interaction between human and computer in general cyber-physical systems would benefit from the support of artificial intelligence (AI) that has the agency to adapt its response based on operator variance. The focus of this paper will be on US operator variance as a first step in demonstrating the concept of AI agency. Recently there has been an explosion of interest in AI across the medical community and many are turning to the growing trend of deep learning (DL) models to assist in diagnosis. However, deep learning models do not perform as well when training data is not fully representative of the problem. Due to this difference in training and deployment, model performance suffers which can lead to misdiagnosis. This issue is known as dataset shift. Two aims to address dataset shift were proposed. The first was to quantify how US operator skill and hardware affects acquired images. The second was to use this skill quantification method to screen and match data to deep learning models to improve performance. A CAE Healthcare BLUE phantom with various mock lesions was scanned by three operators using three different US systems (Siemens S3000, Clarius L15, and Ultrasonix SonixTouch) producing 39013 images. DL models were trained on a specific set to classify the presence of a simulated tumour and tested with data from differing sets. PCA for dimension reduction was applied then K-Means clustering was used to separate images into clusters. This clustering algorithm was then used to screen incoming images during deployment to best match input to an appropriate DL model which is trained specifically to classify that type of operator or hardware. Results showed a noticeable difference when models were given data from differing datasets with the largest accuracy drop being 81.26% to 31.26%. © 2022 IEEE.

Unambiguous discrimination between linearly dependent equidistant states with multiple copies

Item Type Journal Article

Author W.-H. Zhang

Author G. Ren

Abstract Linearly independent quantum states can be unambiguously discriminated, but linearly dependent ones cannot. For linearly dependent quantum states, however, if C copies of the single states are available, then they may form linearly independent states, and can be unambiguously discriminated. We consider unambiguous discrimination among $N = D + 1$ linearly dependent states given that C copies are available and that the single copies span a D -dimensional space with equal inner products. The maximum unambiguous discrimination probability is derived for all C with equal a priori probabilities. For this classification of the linearly dependent equidistant states, our result shows that if C is even then adding a further copy fails to increase the maximum discrimination probability. © 2018, Springer Science+Business Media, LLC, part of Springer Nature.

Abstract Implicit feedback recommendation is challenged by the missing negative feedback essential for effective model training. Existing methods of ten resort to negative sampling, a technique that assumes unlabeled interactions as negative samples. This assumption risks misclassifying potential positive samples within the unlabeled data, thereby undermining model performance. To address this issue, we introduce WeaklyRec, a model-agnostic framework that reframes implicit feedback recommendation as a weakly supervised learning task, eliminating the need for negative samples. However, its unbiasedness hinges on the accurate estimation of the class prior. To address this challenge, we propose Progressive Proximal Transport (PPT), which estimates the class prior by minimizing the proximal transport cost between positive and unlabeled samples. Experiments on three real-world datasets validate the efficacy of WeaklyRec in terms of improved recommendation quality. Code is available at <https://github.com/HowardZJU/weakrec>. © 2025 by the author(s).

Uncertainty analysis on support vector machine for measuring organizational factors in probabilistic risk assessment of nuclear power plants

Item Type Journal Article

Author J. Yang

Author J. Kim

Author P. Farshadmanesh

Author T. Sakurahara

Author S. Reihani

Author C. Blake

Author Z. Mohaghegh

Abstract This paper is a product of a line of research by the authors to explicitly incorporate organizational factors into the probabilistic risk assessment (PRA) of complex socio-technical systems. This explicit incorporation helps (i) assess the system risk due to organizational and managerial weaknesses, (ii) identify the critical organizational root causes of failure scenarios, aiding in effective corrective action, and (iii) avoid the potential of underestimating the system risk involving human error and organizational factors. To facilitate the measurement of organizational factors contributing to the PRA scenarios, the previous studies by the authors developed the Data-Theoretic methodology, where “data analytics” are guided by a “theory” of underlying causation to prevent misleading results from solely data-oriented approaches. The Data-Theoretic methodology consists of two submodules: (a) DT-BASE that develops a detailed causal model based on a theory-building process and is equipped with a baseline quantification utilizing analyst interpretation of information extracted from relevant references; and (b) DT-SITE that conducts data analytics (text mining using machine learning) to quantify the organizational causal elements based on industry event databases. This article investigates uncertainty analysis for the uncertainties associated with machine learning-based data mining in DT-SITE using a Support Vector Machine (SVM) classifier for industry event databases. This article conducts a literature review and proposes a categorization scheme of the SVM uncertainties to establish a theoretical foundation for identifying uncertainty sources associated with the SVM classifier. The implementation of uncertainty analysis for DT-SITE is then illustrated using a nuclear power plant case study. The potential uncertainty sources related to the SVM classifier used in DT-SITE are identified using the categorization scheme developed based on the literature review. The uncertainty analysis procedure for the SVM classifier in DT-SITE is proposed, and the linkage to the current uncertainty analysis process in PRA is discussed. The proposed uncertainty analysis procedure for the SVM classifier in DT-SITE is applied to the illustrative case study to assess the impact of one of the potential uncertainty sources (i.e., the selection of document sections included in the dataset) on the risk-informed decision-making. © 2022 Elsevier Ltd

Uncertainty assessment of proarrhythmia predictions derived from multi-level in silico models

Item Type Journal Article

Author K. Kopańska

Author P. Rodríguez-Belenguer

Author J. Llopis-Lorente

Author B. Trenor

Author J. Saiz

Author M. Pastor

Abstract In silico methods can be used for an early assessment of arrhythmogenic properties of drug candidates. However, their use for decision-making is conditioned by the possibility to estimate the predictions' uncertainty. This work describes our efforts to develop uncertainty quantification methods for the predictions produced by multi-level proarrhythmia models. In silico models used in this field usually start with experimental or predicted IC50 values that describe drug-induced ion channel blockade. Using such inputs, an electrophysiological model computes how the ion channel inhibition, exerted by a drug in a certain concentration, translates to an altered shape and duration of the action potential in cardiac cells, which can be represented as arrhythmogenic risk biomarkers such as the APD90. Using this framework, we identify the main sources of aleatory and epistemic uncertainties and propose a method based on probabilistic simulations that replaces single-point estimates predicted using multiple input values, including the IC50s and the electrophysiological parameters, by distributions of values. Two selected variability types associated with these inputs are then propagated through the multi-level model to estimate their impact on the uncertainty levels in the output, expressed by means of

intervals. The proposed approach yields single predictions of arrhythmogenic risk biomarkers together with value intervals, providing a more comprehensive and realistic description of drug effects on a human population. The methodology was tested by predicting arrhythmogenic biomarkers on a series of twelve well-characterised marketed drugs, belonging to different arrhythmogenic risk classes. © 2023, The Author(s).

Uncertainty estimation of deep learning models for atrial fibrillation detection from Holter recordings: A benchmark study

Item Type Journal Article

Author M.M. Rahman

Author M.W. Rivolta

Author F. Badilini

Author R. Sassi

Abstract With the development of deep learning (DL)-based methods, automated atrial fibrillation (AF) detection from electrocardiograms (ECGs) has recently gained much attention. Although the performance of DL has been encouraging, the susceptibility of DL models to overfitting would benefit from the exploration of uncertainty quantification (UQ) to ensure safe integration into clinical practice. However, there has been limited exploration of UQ methods in the context of DL models for AF detection using Holter ECG recordings, and a comprehensive comparison of various UQ techniques remains absent. This study addressed this gap by introducing a benchmark study wherein 11 distinct UQ methods were rigorously evaluated and compared across three public Holter repositories: IRIDIA-AF, Long-Term AF, and MIT-BIH AF datasets. A residual DL model was used for the UQ methods, which is one of the most common architectures in this domain for its ability to capture complex patterns within ECG data. The findings revealed that batch-ensemble (BE) and packed-ensemble (PE) outperformed other UQ methods concerning both performance, as quantified by sensitivity, specificity and expected calibration error, and computational efficiency. In addition, when we implemented reject inference to discard ECG segments where the model confidence was not sufficiently high, BE and PE still showed to reject the least number of samples, while retaining the highest detection performance. © 2025

Uncertainty Nonlinearly Guided Learning Framework for Full-Wave Inverse Scattering

Item Type Journal Article

Author S. He

Author L. Jin

Author L. Pan

Author X. Li

Author Z. Wei

Abstract Recently, deep learning schemes have been widely used in electromagnetic society. However, different from traditional methods constrained by physics models, the predicted results of these "black-box" neural networks are not reliable, and the prediction errors of networks can only be obtained when ground truths are known, which severely limits the applications of learning-based solvers. Consequently, uncertainty quantifications (UQs) are introduced in learning-based electromagnetic solvers to provide a confidence level. In this work, by incorporating the properties of physical setup in inverse scattering problems (ISPs), an equivariance-based uncertainty quantification (EUQ) method is first proposed, where the diversities caused by different antennas are utilized to quantify the model uncertainty with virtual experiments. More importantly, the quantified uncertainties further serve as nonlinear guidances in ISP learning solvers, which makes it flexible to adaptively choose targeted reconstruction regions. It is shown by intensive tests that the proposed EUQ has a better correlation with the true error compared with traditional UQ methods. The learning framework nonlinearly guided by EUQ also shows much better performance and achieves better predictions in target selected areas in both numerical and experimental tests. © 1963-2012 IEEE.

Abstract This paper presents methods for prominence classification in conversational speech. Most existing tools rely on prosodic features extracted at syllable- or phone-level, performing well on read speech. This is not the case for conversational speech, where the quality of automatic segmentation is significantly worse. We introduce entropy-based chroma features, requiring only word-level segmentations. They perform equally well as a random forest classifier with prosodic features (requiring phone-level segmentation), with accuracies in the range of the human inter-rater agreement. We further use Bayesian deep learning to quantify the epistemic and aleatoric uncertainty of the prediction for prosodic and chroma features. Whereas the aleatoric uncertainty is, as expected, consistent with inter-rater agreement and similarly high for both feature sets, the epistemic uncertainty is lower for the classifier based on chroma features, indicating higher classification consistency across the corpus. © 2025 IEEE.

Uncertainty propagation from sensor data to deep learning models in autonomous driving

Item Type Journal Article

Author Y. Wang

Author T. Wang

Author T. Yue

Abstract Context: Deep learning has been widely used in Autonomous Driving Systems (ADS). Though significant progress has been made regarding their efficiency and accuracy, uncertainty remains a critical factor affecting ADS safety. Such uncertainties are often due to environmental noise and/or imperfect algorithm structures. Studies on uncertainty quantification mostly focus on single classification tasks and overlook how uncertainties propagate from the perception to downstream decision-making, studying of which is critical, as the interplay between perception and decision-making can significantly impact the overall safety of ADS. Objectives: We quantify and understand the uncertainty propagation from sensor data to deep learning models, as well as its impact on ADS safety. Methods: We present an empirical study that quantifies both aleatoric and epistemic uncertainties and assesses how such uncertainties propagate and impact ADS safety under various sensor noise conditions. We also investigate the suitability of two epistemic uncertainty quantification methods (i.e., MC Dropout and Deep Ensembles) to ADS tasks and their cost-effectiveness in selecting highly-uncertain samples. Results: Results show that increased noise can significantly increase uncertainty and degrade model performance, thereby compromising decision-making and potentially impacting ADS safety. Both MC Dropout and Deep Ensembles effectively measure the model's epistemic uncertainty, with MC Dropout showing higher correlation with ADS safety, and saving time and computational costs. Moreover, there are significant differences in the highly-uncertain samples they identified. Conclusion: Our results show the importance of considering uncertainty propagation to ensure the ADS safety. Compared to Deep Ensembles, MC Dropout's efficiency makes it a more suitable choice in the context of ADS. © 2025 Elsevier B.V.

Uncertainty quantification and explainable AI in orthopaedic imaging: A timely call to action

Item Type Journal Article

Author A.P. Tafti

Author Q. Gu

Author J.F. Plate

Abstract Artificial intelligence (AI) has made a big leap in orthopaedic imaging, with deep learning models achieving remarkable accuracy in tasks such as knee osteoarthritis classification and grading, fracture detection, and implant assessment. Yet accuracy in AI models alone is insufficient for clinical trust, adoption, and uptake. Orthopaedic decision-making often carries high risk settings, where any misclassification or overconfidence can have significant consequences for treatment recommendations and patient outcomes. Despite this reality, most current AI models operate as “close boxes”, providing predictions without clarifying their reasoning or quantifying uncertainty. This forum article argues that the integration of uncertainty quantification and explainable AI is no longer optional, but a timely call to action for the orthopaedic community. Uncertainty quantification methods can highlight when predictions are unreliable, prompting confirmatory testing or human oversight, while

explainable AI techniques provide transparency into model reasoning, enabling surgeons and radiologists to better interpret AI outputs. Together, these advances are essential components of trustworthy AI, bridging the gap between technical innovation and real-world orthopaedic practice. By embracing uncertainty-aware and explainable AI models, orthopaedic imaging can move beyond accuracy toward accountability, responsibility, and safer integration into clinical workflows. The time to act is now. © 2025 Delhi Orthopedic Association. All rights are reserved, including those for text and data mining, AI training, and similar technologies.

Uncertainty Quantification and Quality Control for Heatmap-Based Landmark Detection Models

Item Type Journal Article

Author Y. Feng

Author J. Yang

Author L. Tang

Author S. Sun

Author Y. Wang

Abstract Uncertainty quantification is a vital aspect of explainable artificial intelligence that fosters clinician trust in medical applications and facilitates timely interventions, leading to safer and more reliable outcomes. Although deep learning models have reached clinically acceptable accuracy in anatomical landmark detection, their predictions remain susceptible to contextual noise due to the small size of the target structures, making uncertainty quantification more challenging than in classification and segmentation tasks. This paper presents an end-to-end uncertainty quantification method tailored for heatmap-based anatomical landmark detection models, designed to improve both interpretability and controllability in clinical applications. Leveraging Dempster-Shafer Theory and Subjective Logic Theory, we implement probability assignment and uncertainty quantification through a single forward pass to ensure computational efficiency. We introduce an evidence map that captures the strength of landmark evidence, alongside an uncertainty map that calibrates predicted probabilities within the Subjective Logic framework. The interaction between these two components, facilitated by a cross-attention mechanism, further improves landmark detection accuracy and enhances the effectiveness of uncertainty quantification. Experimental results demonstrate that the proposed method maintains detection accuracy, even in noisy environments, while outperforming state-of-the-art methods in terms of uncertainty quantification and quality control. Furthermore, the model effectively identifies out-of-distribution data solely through calibrated probabilities when encountering inconsistencies in multi-center data and novel data, underscoring its potential for clinical applications. © 1982-2012 IEEE.

Abstract We explore the application of uncertainty quantification methods to agent-based models (ABMs) using a simple sheep and wolf predator-prey model. This work serves as a tutorial on how techniques like emulation can be powerful tools in this context. We also highlight the importance of advanced statistical methods in effectively utilising computationally expensive ABMs. Specifically, we implement stochastic Gaussian processes, Gaussian process classification, sequential design, and history matching to address uncertainties in model input parameters and outputs. Our results show that these methods significantly enhance the robustness, accuracy, and predictive power of ABMs. © The Author(s), under exclusive license to Springer Nature Switzerland AG 2025.

Abstract In medical decision-making, clinicians must choose between different time-varying treatment strategies. Counterfactual prediction via g-computation enables comparison of alternative outcome distributions under such treatment strategies. While deep learning can better model high-dimensional data with complex temporal dependencies, incorporating model uncertainty into predicted conditional counterfactual distributions remains challenging. We propose a principled approach to model uncertainty in deep learning implementations of g-computations using approximate Bayesian posterior predictive distributions of counterfactual outcomes via variational dropout and deep ensembles. We evaluate these methods by comparing their counterfactual predictive calibration and performance in decision-making tasks, using two simulated datasets from mechanistic models and a real-world sepsis dataset. Our findings suggest that the proposed uncertainty quantification approach improves both calibration and decision-making performance, particularly in minimizing risks of worst-case adverse clinical outcomes under alternative dynamic treatment regimes. To our knowledge, this is the first work to propose and compare multiple uncertainty quantification methods in machine learning models of g-computation in estimating conditional treatment effects under dynamic treatment regimes. © 2024 L. Abstract Given the sparse uncertainty and highly imbalanced distribution of origin-destination demand in ride-sourcing, probabilistic prediction methods offer rich information to enhance operation decision-making reliability. However, existing uncertainty quantification methods face critical limitations: parametric approaches struggle with irregularities of real-world demand distributions. In contrast, nonparametric methods based on quantile regression are scarcely implemented and suffer from quantile crossing, compromising probabilistic consistency. Furthermore, current approaches seldom consider the crucial inter-service correlations among ride-sourcing services. This paper introduces the Spatiotemporal Mixture-of-Experts Residual-based Multi-quantile Regressive Network (ST-MoE-RMQRN). The implementation is available at <https://github.com/crimsonduanyu/MoE-UQ>. This novel hybrid framework integrates distribution-free quantile estimation with service correlation modeling. Our three main contributions are: 1) a Residual-based Multi-quantile Regressor that employs monotonicity-constrained residual fitting to ensure non-crossing quantiles while preserving distributional flexibility; 2) an environment-aware MoE architecture that captures service correlations through multiple shared-expert networks, addressing potential demand switches among service modals with sensitivity to temporal heterogeneity and exogenous contextual factors such as weather conditions; 3) comprehensive validation on two real-world ride-sourcing datasets demonstrating that our approach consistently outperforms recent probabilistic predictive models in both deterministic and probabilistic forecast metrics, including the Spatiotemporal Zero-Inflated Negative Binomial Graph Neural Network (STZINB-GNN). Additionally, data-wise and component-wise ablation studies confirm the effectiveness of the entire framework and each part of it, showing that explicitly modeling inter-service dependencies substantially improves both deterministic accuracy and probabilistic calibration. Our model is highly efficient in representing extreme demand fluctuations and data-sparse scenarios, which promise to address existing operational inefficiencies faced by transitioning Transportation Network Companies from reactive to anticipatory decision-making. © 2025 Elsevier Ltd. Abstract Large language models (LLMs) power many NLP applications; yet, they can produce fluent but incorrect content (hallucinations), which threatens reliability and user trust. This tutorial introduces uncertainty quantification (UQ) for text generation: methods that attach an explicit reliability signal to model outputs and enable practical safeguards such as hallucination detection and selective generation. We begin with core uncertainty concepts and explain why techniques that work well for classification do not directly transfer to autoregressive generation. We then survey representative white-box and black-box approaches, from entropy- and probability-based scores to learned probes that leverage internal representations. Retrieval-augmented generation (RAG) has become a core design pattern for LLM applications. Incorporating retrieved evidence introduces both new challenges and valuable structures for uncertainty estimation. In the ECIR edition of the tutorial, we focus on UQ techniques tailored to RAG pipelines and briefly discuss how uncertainty can guide agentic workflows. Practical demonstrations are done using LM-Polygraph (<https://github.com/IINemo/lm-polygraph>), an open-source toolkit that consolidates more than forty recent UQ and calibration methods and provides a large-scale benchmark, making it easy to reproduce results and integrate UQ into applications with minimal code. Overall, the tutorial is intended to lower the barrier to entry for researchers and developers who want to evaluate existing UQ methods, design improved ones, and deploy uncertainty-aware LLM systems. © The Author(s), under exclusive license to Springer Nature Switzerland AG 2026.

Uncertainty Quantification for Machine Learning Output Assurance using Anomaly-based Dataset Dissimilarity Measures

Item Type Conference Paper

Author G. Incorvaia

Author D. Hond

Author H. Asgari

Abstract The use of Machine Learning (ML) models as predictive tools has increased dramatically in recent years. However, data-driven systems (such as ML models) exhibit a degree of uncertainty in their predictions. In other words, they could produce unexpectedly erroneous predictions if the uncertainty stemming from the data, choice of model and model parameters is not taken into account. In this paper, we introduce a novel method for quantifying the uncertainty of the performance levels attained by ML classifiers. In particular, we investigate and characterize the uncertainty of model accuracy when classifying out-of-distribution data that is statistically dissimilar from the data employed during training. A main element of this novel Uncertainty Quantification (UQ) method is a measure of the dissimilarity between two datasets. We introduce an innovative family of data dissimilarity measures based on anomaly detection algorithms, namely the Anomaly-based Dataset Dissimilarity (ADD) measures. These dissimilarity measures process feature representations that are derived from the activation values of neural networks when supplied with dataset items. The proposed UQ method for classification performance employs these dissimilarity measures to estimate the classifier accuracy for out-of-distribution datasets, and to give an uncertainty band for those estimates. A numerical analysis of the efficacy of the UQ method is conducted. The obtained results generally demonstrate that the amplitude of the uncertainty band tends to increase as the data dissimilarity measure increases. Overall, this research contributes to the verification and run-time performance prediction of systems composed of ML-based elements. © 2023 IEEE.

Uncertainty Quantification for Markov Random Fields

Item Type Journal Article

Author P. Birmpa

Author M.A. Katsoulakis

Abstract We present an information-based uncertainty quantification method for general Markov random fields (MRFs). MRFs are structured, probabilistic graphical models over undirected graphs and provide a fundamental unifying modeling tool for statistical mechanics, probabilistic machine learning, and artificial intelligence. Typically, MRFs are complex and high-dimensional with nodes and edges (connections) built in a modular fashion from simpler, low-dimensional probabilistic models and their local connections; in turn, this modularity allows one to incorporate available data to MRFs and efficiently simulate them by leveraging their graph-theoretic structure. Learning graphical models from data and/or constructing them from physical modeling and constraints necessarily involves uncertainties inherited from data, modeling choices, or numerical approximations. These uncertainties in the MRF can be manifested either in the graph structure or the probability distribution functions and necessarily will propagate in predictions for quantities of interest. Here we quantify such uncertainties using tight, information-based bounds on the predictions of quantities of interest; these bounds take advantage of the graphical structure of MRFs and are capable of handling the inherent high dimensionality of such graphical models. We demonstrate our methods in MRFs for medical diagnostics and statistical mechanics models. In the latter, we develop uncertainty quantification bounds for finite-size effects and phase diagrams, which constitute two of the typical prediction goals of statistical mechanics modeling. © 2021 Society for

Abstract In the realm of computational science, metamodels serve as indispensable tools for approximating complex systems, facilitating the exploration of scenarios where traditional modelling may prove computationally infeasible. However, the inherent uncertainties within these metamodels, particularly those driven by Machine Learning (ML), necessitate rigorous quantification to ensure reliability and robustness in decision-making processes. One alternative of obtaining uncertainty estimates is using ML models that have a native notion of uncertainty, such as the Bayesian Neural Networks (BNNs), however its repeated sampling necessary to approximate the output distribution is computationally demanding and might defeat the purpose of building metamodels in the first place. In datasets with multidimensional input space and a limited amount of training examples, error estimates provided by BNNs often have poor quality. This study explores alternative empirical approaches to uncertainty quantification, based on knowledge extraction from output space as opposed to input space. Leveraging patterns of magnitude of error committed by the metamodel in output space, we obtain significant improvement of adaptivity of prediction intervals, both over pure Conformal Prediction (CP) and BNNs. Our findings underscore the potential of integrating diverse uncertainty quantification methods to fortify reliability of metamodels, highlighting their robust and quantifiable confidence in model predictions. © 2024 M. Abstract Machine learning is increasingly applied to Earth Observation (EO) data to obtain datasets that contribute towards international accords. However, these datasets contain inherent uncertainty that needs to be quantified reliably to avoid negative consequences. In response to the increased need to report uncertainty, we bring attention to the promise of conformal prediction within the domain of EO. Unlike previous uncertainty quantification methods, conformal prediction offers statistically valid prediction regions while concurrently supporting any machine learning model and data distribution. To support the need for conformal prediction, we reviewed EO datasets and found that only 22.5% of the datasets incorporated a degree of uncertainty information, with unreliable methods prevalent. Current open implementations require moving large amounts of EO data to the algorithms. We introduced Google Earth Engine native modules that bring conformal prediction to the data and compute, facilitating the integration of uncertainty quantification into existing traditional and deep learning modelling workflows. To demonstrate the versatility and scalability of these tools we apply them to valued EO applications spanning local to global extents, regression, and classification tasks. Subsequently, we discuss the opportunities arising from the use of conformal prediction in EO. We anticipate that accessible and easy-to-use tools, such as those provided here, will drive wider adoption of rigorous uncertainty quantification in EO, thereby enhancing the reliability of downstream uses such as operational monitoring and decision-making. © The Author(s) 2024.

Uncertainty Quantification for Safe and Reliable Autonomous Vehicles: A Review of Methods and Applications

Item Type Journal Article**Author** K. Wang**Author** C. Shen**Author** X. Li**Author** J. Lu

Abstract In the past decade, deep learning has been widely applied across various fields. However, its applicability in open-world scenarios is often limited due to the lack of quantifying uncertainty in both data and models. In recent years, a multitude of uncertainty quantification (UQ) approaches for neural networks have emerged and found applications in safety-critical domains such as autonomous vehicles and medical analysis. This paper aims to review the latest advancements in UQ methods and investigate their application specifically in the field of computer vision and autonomous vehicles. Initially, we identify several key qualifications, namely practicability, robustness, accuracy, scalability, and efficiency (referred to as PRASE), and employ them as evaluation criteria throughout this study. By considering these criteria as uniform measurements, we meticulously evaluate and compare the performance of different types of UQ methods, including Bayesian methods, ensemble methods, and single deterministic methods. Furthermore, we delve into the discussion of their application in diverse tasks within the autonomous vehicle domain, such as semantic segmentation, object detection, depth estimation, and end-to-end control. Through comprehensive analysis and comparison, we identify a range of challenges and propose future research directions in this field. Our findings shed light on the importance of addressing uncertainty quantification in deep learning

models and provide insights into enhancing the reliability and performance of autonomous vehicles in real-world scenarios. © 2000-2011 IEEE.

Abstract This half-day tutorial introduces modern techniques for practical uncertainty quantification specifically in the context of multi-class and multi-label text classification. First, we explain the usefulness of estimating aleatoric uncertainty and epistemic uncertainty for text classification models. Then, we describe several state-of-the-art approaches to uncertainty quantification and analyze their scalability to big text data: Virtual Ensemble in GBDT, Bayesian Deep Learning (including Deep Ensemble, Monte-Carlo Dropout, Bayes by Backprop, and their generalization Epistemic Neural Networks), as well as Evidential Deep Learning (including Prior Networks and Posterior Networks). Next, we discuss typical application scenarios of uncertainty quantification in text classification (including in-domain calibration, cross-domain robustness, and novel class detection). Finally, we list popular performance metrics for the evaluation of uncertainty quantification effectiveness in text classification. Practical hands-on examples/exercises are provided to the attendees for them to experiment with different uncertainty quantification methods on a few real-world text classification datasets such as CLINC150. © 2023, The Author(s), under exclusive license to Springer Nature Switzerland AG.

Uncertainty Quantification in Deep Learning

Item Type Conference Paper**Author** L. Kong**Author** H. Kamarthi**Author** P. Chen**Author** B.A. Prakash**Author** C. Zhang

Abstract Deep neural networks (DNNs) have achieved enormous success in a wide range of domains, such as computer vision, natural language processing and scientific areas. However, one key bottleneck of DNNs is that they are ignorant about the uncertainties in their predictions. They can produce wildly wrong predictions without realizing, and can even be confident about their mistakes. Such mistakes can cause misguided decisions-sometimes catastrophic in critical applications, ranging from self-driving cars to cyber security to automatic medical diagnosis. In this tutorial, we present recent advancements in uncertainty quantification for DNNs and their applications across various domains. We first provide an overview of the motivation behind uncertainty quantification, different sources of uncertainty, and evaluation metrics. Then, we delve into several representative

uncertainty quantification methods for predictive models, including ensembles, Bayesian neural networks, conformal prediction, and others. We go on to discuss how uncertainty can be utilized for label-efficient learning, continual learning, robust decision-making, and experimental design. Furthermore, we showcase examples of uncertainty-aware DNNs in various domains, such as health, robotics, and scientific machine learning. Finally, we summarize open challenges and future directions in this area. © 2023 Owner/Author.

Uncertainty quantification in hydrogen production systems design: A review

Item Type Journal Article

Author M.K. Marvin

Author E.O. Agbasi

Author E.N. Aminaho

Author M.D. Aminu

Abstract The increasing demand for hydrogen as an energy carrier highlights the need for efficient and scalable production systems. The performance and feasibility of these technologies are, however, strongly influenced by uncertainties in system parameters, operational conditions, and model inputs, which often limit large-scale deployment. This review provides a critical evaluation of uncertainty quantification techniques applied to hydrogen production systems. We examine key computational modelling approaches that integrate uncertainty quantification methods to improve predictive accuracy, guide process optimization, and support informed decision-making. Despite these advances, it is clearly indicative that many studies continue to employ simplified probability distributions due to the scarcity of high-quality empirical data, particularly for emerging technologies such as solid oxide electrolysis cells, photoelectrochemical systems, and advanced biomass gasifiers. Also, a lack of standardized uncertainty protocols and inconsistencies in hydrogen production modeling assumptions present challenges to reproducibility and cross-study comparison. Addressing this limitation requires greater emphasis on experimental validation and systematic data collection, which will strengthen the credibility of model-based insights and accelerate the scale-up of hydrogen production technologies. Harmonizing modeling frameworks and reporting practices across the hydrogen research community will also be critical to improving benchmarking and ensuring that findings translate effectively into investment and policy strategies. To this end, we aim to highlight pathways toward more reliable, cost-effective, and sustainable hydrogen production systems. © 2026 Elsevier Ltd

Abstract On top of machine learning (ML) models, uncertainty quantification (UQ) functions as an essential layer of safety assurance that could lead to more principled decision making by enabling sound risk assessment and management. The safety and reliability improvement of ML models empowered by UQ has the potential to significantly facilitate the broad adoption of ML solutions in high-stakes decision settings, such as healthcare, manufacturing, and aviation, to name a few. In this tutorial, we aim to provide a holistic lens on emerging UQ methods for ML models with a particular focus on neural networks and the applications of these UQ methods in tackling engineering design as well as prognostics and health management problems. Towards this goal, we start with a comprehensive classification of uncertainty types, sources, and causes pertaining to UQ of ML models. Next, we provide a tutorial-style description of several state-of-the-art UQ methods: Gaussian process regression, Bayesian neural network, neural network ensemble, and deterministic UQ methods focusing on spectral-normalized neural Gaussian process. Established upon the mathematical formulations, we subsequently examine the soundness of these UQ methods quantitatively and qualitatively (by a toy regression example) to examine their strengths and shortcomings from different dimensions. Then, we review quantitative metrics commonly used to assess the quality of predictive uncertainty in classification and regression problems. Afterward, we discuss the increasingly important role of UQ of ML models in solving challenging problems in engineering design and health prognostics. Two case studies with source codes available on GitHub are used to demonstrate these UQ methods and compare their performance in the life prediction of lithium-ion batteries at the early stage (case study 1) and the remaining useful life prediction of turbofan engines (case study 2). © 2023 Elsevier Ltd

Uncertainty Quantification in Machine Learning Solutions for Near-Field Microwave Imaging

Item Type Conference Paper
Author K. Narendra
Author B. Martin
Author J. Carneiro

Author C. Gilmore

Author I. Jeffrey

Abstract Three machine-learning-based uncertainty quantification methods for microwave imaging are reviewed and compared. Measurement data from a model of a 2-D near-field microwave imaging chamber is passed to a data-to-image neural network to produce a reconstruction of a target. First, we consider two methods that create an uncertainty map of the reconstructed target. We demonstrate that uncertainty maps correspond well with the true error when the test example is well represented by the targets in the training set, but the maps do not produce a meaningful representation of the true error when the test target lies out-of-range of the training data (e.g. the target is of drastically different shape or physical properties). In the third method, two autoencoder-based approaches (autoencoding the data versus autoencoding the image) are reviewed to demonstrate their ability to detect whether a given test example is in-range for a given model. The value of combining uncertainty maps with autoencoder-based approaches is discussed. © 2025 IEEE.

Uncertainty quantification in medical image synthesis

Item Type Journal Article**Author** R. Barbano**Author** S. Arridge**Author** B. Jin**Author** R. Tanno

Abstract Machine learning approaches to medical image synthesis have shown outstanding performance, but often do not convey uncertainty information. In this chapter, we survey uncertainty quantification methods in medical image synthesis and advocate the use of uncertainty for improving clinicians' trust in machine learning solutions. First, we describe basic concepts in uncertainty quantification and discuss its potential benefits in downstream applications. We then review computational strategies that facilitate inference, and identify the main technical and clinical challenges. We provide a first comprehensive review to inform how to quantify, communicate and use uncertainty in medical synthesis applications. © 2022 Elsevier Inc. All rights reserved.

Uncertainty Quantification in Molecular Machine Learning for Property Predictions under Data Shifts

Item Type Journal Article**Author** R. Parrondo-Pizarro**Author** J. Lanini**Author** R. Rodríguez-Pérez

Abstract Drug discovery and medicinal chemistry efforts are increasingly influenced by machine learning (ML), with compound property prediction as a central application. ML models have demonstrated strong performance in predicting various compound properties from chemical structure. However, these models can exhibit varying levels of prediction error, making uncertainty quantification (UQ) essential for informed decisions. Standard UQ metrics include the distance to the molecules in the training set and prediction variance, obtained through methods such as model ensembles or Bayesian modeling. Although several UQ methodologies have been developed in recent years, no single approach consistently outperformed others. Herein, we present a comprehensive benchmark of UQ strategies for ML-based prediction of absorption, distribution, metabolism, and excretion (ADME) properties, using both in-house and public data sets. We employed the recently introduced UNIQUE (UNCertaInty QUantification bEnchmarking) framework and evaluated UQ method performance under data shifts. Our findings indicate data-based UQ metrics (e.g., chemical distance), and model-based UQ metrics (e.g., predicted value and variance) may capture complementary aspects of uncertainty. Their combination through error models, designed to predict the original ML model's error, yielded higher-quality uncertainty estimates. These error models emerged as a promising strategy for enhancing UQ, showing robustness in under various degrees and types of data shift. Taken together, our work highlights the potential of combining diverse UQ metrics and error modeling to improve reliability in molecular property prediction. By establishing standardized evaluation setups and assessing UQ under data shifts, we provide a foundation for future UQ method development and benchmarking in the field. © 2026 The Authors. Uncertainty Quantification in Pairwise Difference Learning for Classification

Item Type Journal Article**Author** M.K. Belaid**Author** M. Rabus**Author** E. Hüllermeier

Abstract Instead of learning a mapping from instances to outcomes in the standard way, the key idea of pairwise difference learning (PDL) is to learn a function that takes two instances as input and predicts the difference between their respective outcomes. Given a function of this kind, predictions for a query instance are derived from every training example and then aggregated. We consider pairwise difference learning for classification (PDC) and propose two uncertainty quantification methods that faithfully represent and measure the classifier's predictive uncertainty. Building on recent work on decomposing total uncertainty into aleatoric and epistemic components, we propose different ways of extending corresponding measures to the setting of PDC, depending on how and to what extent the underlying base learner represents uncertainty. In large-scale empirical studies, we analyze both the predictive accuracy and the uncertainty awareness of the methods. © The Author(s), under exclusive licence to Springer Science+Business Media LLC, part of Springer Nature 2025.

Abstract Accurate automated medical image recognition, including classification and segmentation, is one of the most challenging tasks in medical image analysis. Recently, deep learning methods have achieved remarkable success in medical image classification and segmentation, clearly becoming the state-of-the-art methods. However, most of these methods are unable to provide uncertainty quantification (UQ) for their output, often being overconfident, which can lead to disastrous consequences. Bayesian Deep Learning (BDL) methods can be used to quantify uncertainty of traditional deep learning methods, and thus address this issue. We apply three uncertainty quantification methods to deal with uncertainty during skin cancer image classification. They are as follows: Monte Carlo (MC) dropout, Ensemble MC (EMC) dropout and Deep Ensemble (DE). To further resolve the remaining uncertainty after applying the MC, EMC and DE methods, we describe a novel hybrid dynamic BDL model, taking into account uncertainty, based on the Three-Way Decision (TWD) theory. The proposed dynamic model enables us to use different UQ methods and different deep neural networks in distinct classification phases. So, the elements of each phase can be adjusted according to the dataset under consideration. In this study, two best UQ methods (i.e., DE and EMC) are applied in

two classification phases (the first and second phases) to analyze two well-known skin cancer datasets, preventing one from making overconfident decisions when it comes to diagnosing the disease. The accuracy and the F1-score of our final solution are, respectively, 88.95% and 89.00% for the first dataset, and 90.96% and 91.00% for the second dataset. Our results suggest that the proposed TWDBDL model can be used effectively at different stages of medical image analysis. © 2021 Elsevier Ltd

Uncertainty Quantification in Table Structure Recognition

Item Type Conference Paper

Author K. Ajayi

Author L. Zhang

Author Y. He

Author J. Wu

Abstract Quantifying uncertainties for machine learning models is a critical step to reduce human verification effort by detecting predictions with low confidence. This paper proposes a method for uncertainty quantification (UQ) of table structure recognition (TSR). The proposed UQ method is built upon a mixture-of-expert approach termed Test-Time Augmentation (TTA). Our key idea is to enrich and diversify the table representations, to spotlight the cells with high recognition uncertainties. To evaluate the effectiveness, we proposed two heuristics to differentiate highly uncertain cells from normal cells, namely, masking and cell complexity quantification. Masking involves varying the pixel intensity to deem the detection uncertainty. Cell complexity quantification gauges the uncertainty of each cell by its topological relation with neighboring cells. The evaluation results based on standard benchmark datasets demonstrate that the proposed method is effective in quantifying uncertainty in TSR models. To our best knowledge, this study is the first of its kind to enable UQ in TSR tasks. Our code and data are available at: <https://github.com/lamps-lab/UQTTA.git>. © 2024 IEEE.

Uncertainty quantification in the Permian Basin using conventional and modified bootstrap methodology

Item Type Journal Article

Author C.O. Okoli

Author S.D. Goddard

Author O.O. Awoleke

Abstract Various uncertainty quantification methodologies are presented using a combination of several deterministic decline curve analysis models and two bootstrapping algorithms. These probabilistic models are applied to 126 sample wells from the Permian basin. Results are presented for 12–72 months of production hindcast given an average well production history of 103 months. Based on the coverage rate and the forecast error (with the coverage rate being more significant in our choice of the best probabilistic models) and using up to one-half of the available production history for a group of sample wells from the Permian Basin, we find that the CBM-SEPD combination is the best probabilistic model for the Central Basin Platform, the MBM-Arps combination is the best probabilistic model for the Delaware Basin, the CBM-Arps is the best probabilistic model for the Midland Basin, and the best probabilistic model for the overall Permian Basin is the CBM-Arps when early time data is used as hindcast and CBM-SEPD for when one-quarter to one-half of the data is used as hindcast. When three-quarters or more of the available production history is used for analysis, the MBM-SEPD probabilistic model is the best combination in terms of both coverage rate and forecast error for all the sub-basins in the Permian. The novelty of this work lies in its extension of bootstrapping methods to other decline curve analysis models. This work also offers the engineer guidance on the best choice of probabilistic model whilst attempting to forecast production from the Permian Basin. © 2023 The Authors

Uncertainty quantification method and application of landslide susceptibility zoning based on fuzzy mathematics

Item Type Journal Article

Author L. Huang

Author G. WEI

Author Z. Li

Author W. Li

Author Y. Zhang

Abstract Landslide susceptibility zoning boundary uncertainty is an important issue that affects the reliable interpretation of landslide susceptibility assessment (LSA). To address the downstream uncertainty introduced by the discretization of continuous susceptibility indices, this study proposes an uncertainty quantification framework integrating fuzzy logic and information entropy theory. A case study in Kang County, Gansu Province, China, the results indicate that: (1) the Random Forest (RF) model achieved satisfactory predictive performance ($AUC = 0.830$), providing a reliable basis for downstream uncertainty quantification; (2) areas with high uncertainty are mainly distributed in the transition zones between different susceptibility levels and in the northeastern part of the county, whereas low uncertainty areas are predominantly distributed in the southern region, with a pronounced clustering pattern in the southwestern; and (3) comparative validation using the Support Vector Machine (SVM) model demonstrates that the spatial patterns of uncertainty are highly consistent across different models, indicating the robustness and applicability of the proposed framework. The results suggest that susceptibility zonation based on classification methods such as Jenks inevitably introduces boundary fuzziness, and the proposed framework can serve as an effective complement to conventional LSA by identifying low reliability areas and providing support for the optimization of susceptibility zonation. © The Author(s) 2026.

Uncertainty quantification of fluidized beds using a data-driven framework

Item Type Journal Article

Author V. Kumar

Author A. Kommu

Abstract We carried out a nondeterministic analysis of flow in a fluidized bed. The flow in the fluidized bed is simulated with National Energy Technology Laboratory's open source multiphase fluid dynamics suite MFiX. It does not possess tools for uncertainty quantification. Therefore, we developed a C++ wrapper to integrate an uncertainty

quantification toolkit developed at Sandia National Laboratory with MFiX. The wrapper exchanges uncertain input parameters and key output parameters among Dakota and MFiX. However, a data-driven framework is also developed to obtain reliable statistics as it is not feasible to get them with MFiX integrated into Dakota, Dakota-MFiX. The data generated from Dakota-MFiX simulations, with the Latin Hypercube method of sampling size 500, is used to train a machine learning algorithm. The trained and tested deep neural network algorithm is integrated with Dakota via the wrapper to obtain low order statistics of the bed height and pressure drop across the bed. In addition, it can be used to obtain statistics with various distributions of the uncertain input variables and various uncertainty quantification methods. In addition, sensitivity analysis is carried out for 9 input parameters and two output parameters. © 2019 Elsevier B.V.

Uncertainty quantification of geochemical data imputation using Monte Carlo dropout

Item Type Journal Article

Author V. Puzyrev

Author P. Duuring

Abstract Machine learning models have shown their promise in geochemical data imputation tasks. However, being black-box solvers, these models require more confidence in their predictions. Using uncertainty quantification methods for deep neural networks can increase the reliability of their predictions. In this paper, we use Monte Carlo Dropout to estimate uncertainty in geochemical data imputation. Multiple forward passes with different dropout configurations yield a predictive distribution for the unknown analytes. The mean of this distribution is used as the prediction, while the standard deviation expresses the uncertainty of the neural networks. Two different scenarios, namely the WACHEM and WAMEX databases containing multi-element geochemical data for rock samples, illustrate the predictive accuracy of the method and its capability to measure the associated uncertainty. Dropout values of 0.1–0.2 were identified as a good balance in prediction accuracy and model uncertainty. © 2025

Uncertainty quantification of graph convolution neural network models of evolving processes

Item Type Journal Article

Author J. Hauth

Author C. Safta

Author X. Huan

Author R.G. Patel

Author R.E. Jones

Abstract The application of neural network models to scientific machine learning tasks has proliferated in recent years. In particular, neural networks have proved to be adept at modeling processes with spatial–temporal complexity. Nevertheless, these highly parameterized models have garnered skepticism in their ability to produce outputs with quantified error bounds over the regimes of interest. Hence there is a need to find uncertainty quantification methods that are suitable for neural networks. In this work we present comparisons of the parametric uncertainty quantification of neural networks modeling complex spatial–temporal processes with Hamiltonian Monte Carlo and Stein variational gradient descent and its projected variant. Specifically we apply these methods to graph convolutional neural network models of evolving systems modeled with recurrent neural network and neural ordinary differential equations architectures. We show that Stein variational inference is a viable alternative to Monte Carlo methods with some clear advantages for complex neural network models. For our exemplars, Stein variational interference gave similar pushed forward uncertainty profiles through time compared to Hamiltonian Monte Carlo, albeit with generally more generous variance. Projected Stein variational gradient descent also produced similar uncertainty profiles to the non-projected counterpart, but large reductions in the active weight space were confounded by the stability of the neural network predictions and the convoluted likelihood landscape. © 2024 Elsevier B.V.

Uncertainty Quantification of Hyperspectral Image Denoising Frameworks Based on Sliding-Window Low-Rank Matrix Approximation

Item Type Journal Article

Author J. Song

Author S. Xia

Author J. Wang

Author M. Patel

Author D. Chen

Abstract Sliding-window-based low-rank matrix approximation (LRMA) is a technique widely used in hyperspectral images (HSIs) denoising or completion. However, the uncertainty quantification of the restored HSI has not been addressed to date. Accurate uncertainty quantification of the denoised HSI facilitates applications such as multisource or multiscale data fusion, data assimilation, and product uncertainty quantification since these applications require an accurate approach to describe the statistical distributions of the input data. Therefore, we propose a prior-free closed-form element-wise uncertainty quantification method for LRMA-based HSI restoration. Our closed-form algorithm overcomes the difficulty of handling uncertainty in HSI patch mixing caused by the sliding-window strategy used in the conventional LRMA process. The proposed approach only requires the uncertainty of the observed HSI and provides the uncertainty result relatively rapidly and with similar computational complexity as the LRMA technique. We conduct extensive experiments to validate the estimation accuracy of the proposed closed-form uncertainty approach. The method is robust to at least 10% random impulse noise at the cost of 10%-20% of additional processing time compared to the LRMA. The experiments indicate that the proposed closed-form uncertainty quantification method is more applicable to real-world applications than the baseline Monte Carlo test, which is computationally expensive. © 1980-2012 IEEE.

Uncertainty Quantification of Microblock-Based Resource Models and Sequencing of Sampling

Item Type Journal Article**Author** G.T. Nwaila**Author** E.J.M. Carranza**Abstract** Spatial models are fundamental across the mineral value chain, forming the basis for exploration and extraction. Geodata science and increasingly bigger data permit alternatives to traditional mineral resource estimation methods, particularly in spatial data interpolation. Interpolation has been formulated as a machine learning (ML)

task, providing new capabilities, such as automated deployment and remote real-time monitoring. However, a significant gap exists regarding how uncertainty propagates through ML workflows. This paper introduces an uncertainty propagation method to a ML-based interpolation method called microblocking that propagates epistemic uncertainty. Our method adheres to the data science framework and is fully ML-based. Epistemic uncertainty is the dominant uncertainty in geosciences, because data sparsity is created by both complex dynamics of physical systems and sampling limitations. Our uncertainty estimates are block-specific and can guide sampling and other activities. Biasing sampling toward blocks with high economic potential and high uncertainty enables the most cost-effective sequencing of sampling. A rapid, ML-based uncertainty quantification method provides a modern data-driven (feedback-based) framework to extraction guidance, built on big data, geodata science, and real-time mineral resource modeling. We compare our method with typical kriging uncertainty estimates and demonstrates that our results are more block-specific and broader in scope (more comprehensive). In an industry where financial stakes are significant, a thorough understanding of uncertainty can improve investor confidence. The method not only improves scientific rigor, but is also engineered to fit increasingly bigger data across the mineral value chain, and caters to the conservative nature of the mineral industry, where method validation occurs at a slower pace. © The Author(s) 2025.

UNCERTAINTY QUANTIFICATION OF PHYSICS-BASED LABEL-FREE DEEP LEARNING AND PROBABILISTIC PREDICTION OF EXTREME EVENTS

Item Type	Conference Paper
Author	H. Li
Author	J. Yin
Author	X. Du
Abstract	Surrogate models from machine learning regression have been increasingly used in engineering analysis and design. Since surrogate models are usually built using data from solving expensive physical models, label-free machine learning methodologies have been developed to reduce the computational cost. Understanding and quantifying the model (epistemic) uncertainty of surrogate models is critical for their applications with quantified confidence. It is, however, much more computationally expensive, or even impossible to quantifying the model uncertainty for label-free machine learning. In this work we propose an uncertainty quantification method for the epistemic uncertainty of physics-based label-free regression. The method is used after a surrogate model has already been built by deep neural network based on the data of only input variables without labels (data of responses) and a system of physical equations. A surrogate model of the neural network regression model error is built with Gaussian Process regression using the existing training points and the derivatives of the system of physical equations at the training points. The error model is then used to compensate the error of the neural network surrogate model, therefore producing more accurate predictions. With higher accuracy, the proposed method is applied to probabilistic prediction of extreme events where both (aleatory) data uncertainty and model uncertainty coexist, and higher accuracy is required. Its application to time-dependent reliability prediction of a four-bar linkage mechanism demonstrates the high accuracy of the proposed method. Copyright © 2022 by ASME.

Author T. Scholten

Abstract Soil organic carbon (SOC) contents and stocks provide valuable insights into soil health, nutrient cycling, greenhouse gas emissions, and overall ecosystem productivity. Given this, remote sensing data coupled with advanced machine learning (ML) techniques have eased SOC level estimation while revealing its patterns across different ecosystems. However, despite these advances, the intricacies of training reliable and yet certain SOC models for specific end-users remain a great challenge. To address this, we need robust SOC uncertainty quantification techniques. Here, we introduce a methodology that leverages conformal prediction to address the uncertainty in estimating SOC contents while using remote sensing data. Conformal prediction generates statistically reliable uncertainty intervals for predictions made by ML models. Our analysis, performed on the LUCAS dataset in Europe and incorporating a suite of relevant environmental covariates, underscores the efficacy of integrating conformal prediction with another ML model, specifically random forest. In addition, we conducted a comparative assessment of our results against prevalent uncertainty quantification methods for SOC prediction, employing different evaluation metrics to assess both model uncertainty and accuracy. Our methodology showcases the utility of the generated prediction sets as informative indicators of uncertainty. These sets accurately identify samples that pose prediction challenges, providing valuable insights for end-users seeking reliable predictions in the complexities of SOC estimation. © 2024 by the authors.

Uncertainty Quantification of Stochastic Defects in Materials

Item Type Book

Author L. Chu

Abstract Uncertainty Quantification of Stochastic Defects in Materials investigates the uncertainty quantification methods for stochastic defects in material microstructures. It provides effective supplementary approaches for conventional experimental observation with the consideration of stochastic factors and uncertainty propagation. Pursuing a comprehensive numerical analytical system, this book establishes a fundamental framework for this topic, while emphasizing the importance of stochastic and uncertainty quantification analysis and the significant influence of microstructure defects on the material macro properties. Key Features Consists of two parts: One exploring methods and theories and the other detailing related examples Defines stochastic defects in materials and presents the uncertainty quantification for defect location, size, geometrical configuration, and instability Introduces general Monte Carlo methods, polynomial chaos expansion, stochastic finite element

methods, and machine learning methods Provides a variety of examples to support the introduced methods and theories Applicable to MATLAB® and ANSYS software This book is intended for advanced students interested in material defect quantification methods and material reliability assessment, researchers investigating artificial material microstructure optimization, and engineers working on defect influence analysis and nondestructive defect testing. © 2022 Taylor & Francis Group, LLC.

Uncertainty quantification using Bayesian neural networks in classification: Application to biomedical image segmentation

Item Type Journal Article

Author Y. Kwon

Author J.-H. Won

Author B.J. Kim

Author M.C. Paik

Abstract Most recent research of deep neural networks in the field of computer vision has focused on improving performances of point predictions by developing network architectures or learning algorithms. Reliable uncertainty quantification accompanied by point estimation can lead to a more informed decision, and the quality of prediction can be improved. In this paper, we invoke a Bayesian neural network and propose a natural way of quantifying uncertainties in classification problems by decomposing the moment-based predictive uncertainty into two parts: aleatoric and epistemic uncertainty. The proposed method takes into account the discrete nature of the outcome, yielding the correct interpretation of each uncertainty. We demonstrate that the proposed uncertainty quantification method provides additional insights into the point prediction using two Ischemic Stroke Lesion Segmentation Challenge datasets and the Digital Retinal Images for Vessel Extraction dataset. © 2019 Elsevier

Uncertainty quantification-based robust deep learning for building energy systems considering distribution shift problem

Item Type Journal Article**Author** X. Liang**Author** Z. Liu**Author** J. Wang**Author** X. Jin**Author** Z. Du

Abstract Artificial intelligence becomes one of the key technologies in building energy conservation, where deep learning algorithms provide feasible solution for the modeling problem of complex building energy systems. However, existing deep learning models are lack of robustness under distribution shift scenarios, which greatly limits their real-world application. To tackle this problem, first, we enrich the

concept of distribution shift problem in building energy domain. And a cluster-based dataset splitting method is proposed to simulate the distribution shift scenarios. Second, we adopt uncertainty quantification methods to improve the overall robustness of deep learning model. Comprehensive data experiments are conducted based on the reference modeling problem of chiller, and five widely-used uncertainty quantification methods are compared under distribution shift scenarios. Both the model precision performance and robustness performance are investigated. The experimental result demonstrates that the deep ensemble (DE) model is a simple but efficient method to solve the distribution shift problem, where its precision performance and robustness performance outperformed the other methods, followed by Bayesian neural network (BNN). In addition, the benefit of robust deep learning model is also studied. It is shown that the deep learning model with higher robustness performance can better filter out the unreliable predictions, which is essential to the online active learning strategy. The proposed research framework might provide a solid foundation for the real-world application of deep learning model. © 2023 Elsevier Ltd

Uncertainty study on thermal and energy performances of a deterministic parameters based optimal aerogel glazing system using machine-learning method

Item Type Journal Article

Author Y. Zhou

Author S. Zheng

Abstract Uncertainty and sensitivity analyses of deterministic parameters based optimal aerogel glazing system are necessary due to multi-dimensional uncertainties in the real working condition, whereas thermal and energy performances of aerogel glazing system, in the academia, are normally characterized by deterministic parameters. In this study, a generic uncertainty quantification methodology was proposed using the two-dimensional Markov Chain Monte Carlo to quantify both aleatory and epistemic uncertainties of scenario parameters in the aerogel glazing system. A surrogate model, trained by mathematical heat and optical models using the machine-learning based data-driven method, was developed to predict the thermal and energy performances under multi-level scenario uncertainties. Results showed that, the developed surrogate model is efficient to deal with computational complexity of sophisticated light and heat transfer processes. When considering scenario uncertainties, the annual value of heat flux is reduced from 237.2 to 185.3 kWh/(m².a) by 21.9%, and the annual value of total heat gain is reduced from 267.2 to 209.5 kWh/m².a by 21.6%. This study proposes a generic methodology for multi-dimensional uncertainties' quantification and a surrogate model for thousands of cases-based uncertainty analysis. Approaches for the stochastic uncertainty analysis on aerogel glazing system were presented, which can promote the optimal design in buildings. © 2019 Elsevier Ltd

Uncertainty-Aware AI for Enhanced Chronic Kidney Disease Diagnosis: A Review of Explainable and Reliable Models

Item Type Conference Paper

Author B. Anoch

Author L. Parthiban

Abstract Chronic kidney disease is a progressive condition affecting millions globally, often progressing to end-stage renal disease without early detection and management. Traditional diagnostic methods, relying on serum biomarkers and manual image interpretation, can be time-consuming, subjective, and variable. Artificial intelligence, particularly deep learning, has emerged as a transformative tool, automating CKD detection, classification, and risk prediction using medical imaging modalities like ultrasound, CT, and MRI. This review comprehensively examines AI-driven CKD diagnosis, focusing on deep learning-based image analysis, segmentation techniques, classification models, and uncertainty quantification methods. We explore various architectures, including CNNs, U-Net, Vision Transformers, and hybrid AI models, highlighting their effectiveness in automating kidney segmentation and CKD severity classification. We also discuss uncertainty-aware AI models, emphasizing the importance of model reliability and interpretability for clinical deployment. Despite advancements, challenges remain, including limited annotated datasets, model generalization issues, interpretability concerns, domain shifts, and ethical considerations. Future research should prioritize developing large-scale multi-institutional datasets, integrating multi-modal AI approaches, enhancing explainability through interpretable AI models, and establishing standardized regulatory frameworks for AI-driven CKD diagnosis © 2025 IEEE.

Abstract Nephrotoxicity remains a critical safety concern in drug development and clinical practice. Despite their significance, existing computational models for nephrotoxicity prediction face challenges related to limited precision and reliability. To address these challenges, this study constructed the largest publicly available database to date, comprising 1831 high-quality nephrotoxicity-related compounds. Using this dataset, we developed classification models employing both traditional machine learning algorithms and graph-based deep learning methods. Our results demonstrate that the Directed Message Passing Neural Network model, combined with molecular graphs and ChemoPy2D descriptors, outperformed other models, achieving a mean Kappa value of 70.3%. To improve the reliability of the model, we implemented an uncertainty quantification method to define the model's applicability domain and quantify the confidence of prediction. On the representative model, this approach significantly enhanced predictive performance within the applicability domain, yielding a Kappa metric of 90.4%. Notably, our model also achieved the highest performance on an external test set compared to existing models. Finally, we performed multiscale feature analysis to provide actionable insights for safer drug design. This analysis integrated dataset -centric methods to identify structural alerts and beneficial transformations, alongside model-centric techniques to reveal the key global and local features driving nephrotoxicity. The established prediction models, combined with uncertainty quantification and structural feature insights derived in this study, offer valuable tools for the development of safer and more effective drugs.

Uncertainty-aware deep learning-based CAD system for breast cancer classification using ultrasound and mammography images

Item Type Journal Article

Author M. Chegini

Author A. Mahlooji Far

Abstract Breast cancer is one of the most common types of cancer in women. Early and accurate diagnosis of breast cancer can increase the treatment chances and decrease the mortality rate. Thus, the development of accurate and reliable Computer-Aided Diagnosis (CAD) systems using breast cancer images is an immediate priority for early diagnosis. Deep learning methods have had a widespread role in CAD systems. In spite of the advantages, most deep learning-based CADs cannot quantify the uncertainty of their predictions. Uncertainty in the predicted results from a CAD system might endanger people's life in these crucial steps for breast cancer classification. Therefore, in this study, the Monte Carlo Dropout method is utilised as an uncertainty quantification method. Furthermore, differently from most existing studies, we present an uncertainty-aware deep learning model which can classify accurately from different types of images, namely, mammograms and ultrasound. The results show the proposed model achieved the accuracy of 99.95% in mammogram dataset, namely, DDSM and 98.40% and 91.34% in ultrasound datasets, namely, BUSM and BUSI, respectively. Finally, since we found the proposed model shows high uncertainty in misclassifications, we suggested to use the uncertainty values to find appropriate subsets for further inspection to increase the performance. © 2023 The Author(s). Abstract For many applications, analyzing the uncertainty of a machine learning model is indispensable. While research of uncertainty quantification (UQ) techniques is very advanced for computer vision applications, UQ methods for spatio-temporal data are less studied. In this paper, we focus on models for online handwriting recognition, one particular type of spatio-temporal data. The data is observed from a sensor-enhanced pen with the goal to classify written characters. We conduct a broad evaluation of aleatoric (data) and epistemic (model) UQ based on two prominent techniques for Bayesian inference, Stochastic Weight Averaging-Gaussian (SWAG) and Deep Ensembles. Next to a better understanding of the model, UQ techniques can detect out-of-distribution data and domain shifts when combining right-handed and left-handed writers (an underrepresented group). © 2022 Copyright for this paper by its authors.

Uncertainty-aware fragility modeling of urban building exteriors subjected to hurricane-induced windborne debris with conditional generative adversarial nets

Item Type Journal Article

Author Z. Xiong

Author G. Jia

Author Y. Dong

Author Y. Guo

Abstract Building exteriors are highly susceptible to windborne debris damage during hurricanes, a concern that is growing in urgency amid climate change. Fragility functions that estimate the probability of exterior failure as a function of hurricane intensity are commonly used to assess this risk. However, developing the fragility function often requires numerous calls of expensive physics-based models. To address this challenge, this study proposes a machine learning-based approach that leverages conditional generative adversarial networks (cGAN) and its generative capability to efficiently and accurately develop fragility functions. cGAN model is introduced to model the complex high-dimensional distribution of the maximum impact momentum of windborne debris on the building exterior conditioned on hurricane intensity measures. To ensure the accuracy and reliability of cGAN, a stochastic simulation-guided training strategy is proposed that treats data preparation as an augmented stochastic simulation problem. This approach enhances exploration of the input space and enables the formulation of a novel training performance metric tailored toward fragility modeling. Once trained, the cGAN model can rapidly generate extensive damage realizations under various hurricane scenarios, which facilitates the construction of fragility functions. Furthermore, Monte Carlo dropout is introduced to efficiently quantify the uncertainty of the fragility function established using cGAN. Such uncertainty provides end users with a measure of confidence in the derived fragility estimates. An illustrative example is presented to validate the efficacy of the proposed method. Results show that the proposed performance metric is effective in guiding the selection of a reliable cGAN model that provides satisfactory damage and fragility estimates, and the proposed uncertainty quantification method can help provide rational confidence in the estimates. © 2025 The Authors. Uncertainty-aware generative models for inferring document class prevalence

Item Type Conference Paper

Author K.A. Keith

Author B. O'Connor

Editor Riloff E.

Editor Chiang D.

Editor Hockenmaier J.

Editor Tsujii J.

Abstract Prevalence estimation is the task of inferring the relative frequency of classes of unlabeled examples in a group—for example, the proportion of a document collection with positive sentiment. Previous work has focused on aggregating and adjusting discriminative individual classifiers to obtain prevalence point estimates. But imperfect classifier accuracy ought to be reflected in uncertainty over the predicted prevalence for scientifically valid inference. In this work, we present (1) a generative probabilistic modeling approach to prevalence estimation, and (2) the construction and evaluation of prevalence confidence intervals; in particular, we demonstrate that an off-the-shelf discriminative classifier can be given a generative re-interpretation, by backing out an implicit individual-level likelihood function, which can be used to conduct fast and simple group-level Bayesian inference. Empirically, we demonstrate our approach provides better confidence interval coverage than an alternative, and is dramatically more robust to shifts in the class prior between training and testing.¹ © 2018 Association for Computational Linguistics

Under pressure: Integrating machine learning to quantify clutch moments in American football

Item Type Journal Article

Author A. Aich

Author D. Bhattacharjee

Author H. Saikia

Abstract This study introduces a novel pressure index framework designed to quantify the intensity of crucial moments in an American football game. Our model integrates game-specific metrics such as time remaining, score differential, field position, and play context to establish quantitative measures of pressure on offensive and defensive units. The two proposed indices, viz, the composite offensive pressure index (PIO3) and defensive pressure index (PID) dynamically capture the evolving situational stress during a game. To validate and assess their predictive power, we employ machine learning techniques, including Logistic Regression, Random Forest, and Gradient Boosting models. Using play-by-play data from the 2023 NFL season, the results demonstrate that the ensemble learning methods outperform logistic regression, with Gradient Boosting achieving the highest predictive precision (AUC = 0.944) in forecasting drive success. This machine learning-driven framework provides new insights into situational dynamics and performance under pressure such as identifying pivotal clutch moments and quantifying critical drive transitions offering potential applications in advanced performance analysis, coaching strategies, and sports analytics research. © The Author(s) 2025

Undersampling is a Minimax Optimal Robustness Intervention in Nonparametric Classification

Item Type Journal Article

Author N.S. Chatterji

Author S. Haque

Author T.B. Hashimoto

Abstract While a broad range of techniques have been proposed to tackle distribution shift, the simple baseline of training on an undersampled balanced dataset often achieves close to state-of-the-art-accuracy across several popular benchmarks. This is rather surprising, since under-sampling algorithms discard excess majority group data. To understand this phenomenon, we ask if learning is fundamentally constrained by a lack of minority group samples. We prove that this is indeed the case in the setting of nonparametric binary classification. Our results show that in the worst case, an algorithm cannot outperform undersampling unless there is a high degree of overlap between the train and test distributions (which is unlikely to be the case in real-world datasets), or if the algorithm leverages additional structure about the distribution shift. In particular, in the case of label shift we show that there is always an undersampling algorithm that is minimax optimal. In the case of group-covariate shift we show that there is an undersampling algorithm that is minimax optimal when the overlap between the group distributions is small. We also perform an experimental case study on a label shift dataset and find that in line with our theory, the test accuracy of robust neural network classifiers is constrained by the number of minority samples. © 2023, Transactions on Machine Learning Research. Understanding Hessian Alignment for Domain Generalization

Item Type Conference Paper
Author S. Hemati
Author G. Zhang
Author A. Estiri
Author X. Chen
Abstract Out-of-distribution (OOD) generalization is a critical ability for deep learning models in many real-world scenarios including healthcare and autonomous vehicles. Recently, different techniques have been proposed to improve OOD generalization. Among these methods, gradient-based regularizers have shown promising performance compared with other competitors. Despite this success, our understanding of the role of Hessian and gradient alignment in domain generalization is still limited. To address this shortcoming, we analyze the role of the classifier's head Hessian matrix and gradient in domain generalization using recent OOD theory of transferability. Theoretically, we show that spectral norm between the classifier's head Hessian matrices across domains is an upper bound of the transfer measure, a notion of distance between target and source domains. Furthermore, we analyze all the attributes that get aligned when we encourage similarity between Hessians and gradients. Our analysis explains the success of many regularizers like CORAL, IRM, V-REx, Fish, IGA, and Fishr as they regularize part of the classifier's head Hessian and/or gradient. Finally, we propose two simple yet effective methods to match the classifier's head Hessians and gradients in an efficient way, based on the Hessian Gradient Product (HGP) and Hutchinson's method (Hutchinson), and without directly calculating Hessians. We validate the OOD generalization ability of proposed methods in different scenarios, including transferability, severe correlation shift, label shift and diversity shift. Our results show that Hessian alignment methods achieve promising performance on various OOD benchmarks. The code is available here.

Understanding the complexity of near-infrared quantification of highly porous patient-tailored drug products by utilizing chemometrics and stimulated Raman imaging

Item Type Journal Article

Author I. Ahola

Author T. Tomberg

Author C. Cornett

Author C. Strachan

Author N. Genina

Abstract Additively manufactured drug products, typically produced using small-scale, on-demand batch mode, require rapid and non-destructive quantification methods. A tunable modular design (TMD) approach combining porous polymeric freeze-dried modules and an additive manufacturing method, inkjet printing, was proposed in an earlier study to fabricate accurate and patient-tailored doses of an antidepressant citalopram hydrobromide. This approach addresses the unmet medical needs associated with antidepressant tapering. Non-destructive quantification of printed porous structures is challenging due to the presence of residual solvents and frequent fluctuation of the material density. These shortcomings were mitigated by utilizing a

spinning near-infrared spectroscopy (NIRS) measurement setup and a post-print drying step. A machine learning algorithm (ML), specifically support vector regression, was implemented to lessen potential non-linearities caused by the complex structure of TMD drug products. The non-linear support vector regression models performed better than linear partial least squares (PLS) models when modeling the entire sample set (prediction error improved by 19 %). By dividing the TMD samples into subtypes and creating individual models for each subtype improved model performance: linear PLS models performed better or equally to non-linear models. It was hypothesized that this outcome was due to the structural differences between different TMD sample subtypes that was later confirmed by stimulated Raman scattering (SRS) microscopy. It was demonstrated that for complex porous drug products ML algorithms can improve NIRS model performance when a single universal robust model is preferred, and SRS is a powerful tool to explain the challenges that printing onto porous drug products can introduce to the NIRS quantification. © 2025 The Authors

Understanding the Disparities of PM_{2.5} Air Pollution in Urban Areas via Deep Support Vector Regression

Item Type Journal Article

Author Y. Xia

Author T. McCracken

Author T. Liu

Author P. Chen

Author A. Metcalf

Author C. Fan

Abstract In densely populated urban areas, PM_{2.5} has a direct impact on the health and quality of residents' life. Thus, understanding the disparities of PM_{2.5} is crucial for ensuring urban sustainability and public health. Traditional prediction models often overlook the spillover effects within urban areas and the complexity of the data, leading to inaccurate spatial predictions of PM_{2.5}. We propose Deep Support Vector Regression (DSVR) that models the urban areas as a graph, with grid center points as the nodes and the connections between grids as the edges. Nature and human activity features of each grid are initialized as the representation of each node. Based on the graph, DSVR uses random diffusion-based deep learning to quantify the spillover effects of PM_{2.5}. It leverages random walk to uncover more extensive spillover relationships between nodes, thereby capturing both the local and nonlocal spillover effects of PM_{2.5}. And then it engages in predictive learning using the feature vectors that encapsulate spillover effects, enhancing the understanding of PM_{2.5} disparities and connections across different regions. By applying our proposed model in the northern region of New York for predictive performance analysis, we found that DSVR consistently outperforms other models. During periods of PM_{2.5} surges, the R-square of DSVR reaches as high as 0.729, outperforming non-spillover models by 2.5 to 5.7 times and traditional spatial metric models by 2.2 to 4.6 times. Therefore, our proposed model holds significant importance for understanding disparities of PM_{2.5} air pollution in urban areas, taking the first steps toward a new method that considers both the spillover effects and nonlinear feature of data for prediction. © 2024 American Chemical Society.

Understanding the Role of Layer Normalization in Label-Skewed Federated Learning

Item Type Journal Article

Author G. Zhang

Author M. Beitollahi

Author A. Bie

Author X. Chen

Abstract Layer normalization (LN) is a widely adopted deep learning technique especially in the era of foundation models. Recently, LN has been shown to be surprisingly effective in federated learning (FL) with non-i.i.d. data. However, exactly why and how it works remains mysterious. In this work, we reveal the profound connection between layer normalization and the label shift problem in federated learning. To understand layer normalization better in FL, we identify the key contributing

mechanism of normalization methods in FL, called feature normalization (FN), which applies normalization to the latent feature representation before the classifier head. Although LN and FN do not improve expressive power, they control feature collapse and local overfitting to heavily skewed datasets, and thus accelerates global training. Empirically, we show that normalization leads to drastic improvements on standard benchmarks under extreme label shift. Moreover, we conduct extensive ablation studies to understand the critical factors of layer normalization in FL. Our results verify that FN is an essential ingredient inside LN to significantly improve the convergence of FL while remaining robust to learning rate choices, especially under extreme label shift where each client has access to few classes. Our code is available at https://github.com/huawei-noah/Federated-Learning/tree/main/Layer_Normalization. © 2024, Transactions on Machine Learning Research. All rights reserved.

Undoing the Damage of Label Shift for Cross-domain Semantic Segmentation

Item Type Conference Paper

Author Y. Liu

Author J. Deng

Author J. Tao

Author T. Chu

Author L. Duan

Author W. Li

Abstract Existing works typically treat cross-domain semantic segmentation (CDSS) as a data distribution mismatch problem and focus on aligning the marginal distribution or conditional distribution. However, the label shift issue is unfortunately overlooked, which actually commonly exists in the CDSS task, and often causes a classifier bias in the learnt model. In this paper, we give an in-depth analysis and show that the damage of label shift can be overcome by aligning the data conditional distribution and correcting the posterior probability.

To this end, we propose a novel approach to undo the damage of the label shift problem in CDSS. In implementation, we adopt class-level feature alignment for conditional distribution alignment, as well as two simple yet effective methods to rectify the classifier bias from source to target by remolding the classifier predictions. We conduct extensive experiments on the benchmark datasets of urban scenes, including GTA5 to Cityscapes and SYNTHIA to Cityscapes, where our proposed approach outperforms previous methods by a large margin. For instance, our model equipped with a self-training strategy reaches 59.3% mIoU on GTA5 to Cityscapes, pushing to a new state-of-the-art. The code will be available at https://github.com/manmanjun/Undoing_UDA. © 2022 IEEE.

Author Z. Huang

Author M. Gao

Author J. Xu

Abstract Federated Learning (FL) is a framework designed to enable distributed and privacy-preserving learning. It typically involves a central server coordinating multiple clients to collaboratively train a global model without the need for sharing private data. Recent studies have revealed that this parameter-only communication strategy can be hindered by non-independent and identically distributed (non-iid) data across clients, leading to statistical heterogeneity. This issue necessitates the development of Personalized Federated Learning (PFL), which aims to enhance the performance of individual clients while still allowing for the learning of a global model. Most existing work on PFL has focused on label shift in supervised tasks, with relatively little attention given to feature shift, another common problem in real-world applications of federated learning. For instance, client data may vary in terms of illumination, angles, and quality for natural images, or in imaging protocols for medical images. To address this issue, we propose a general yet powerful framework that leverages the geometric interpretation of deep neural networks. Geometrically, a deep neural network partitions the feature space into a Power Diagram (PD) or Voronoi Diagram (VD). Regularized losses are introduced to mitigate feature shift from the perspective of PD and VD. Additionally, a personalized generator network is formulated for each client to rectify feature distribution and adapt the input data from its own domain to an "averaged" or unified domain that generalizes well across all clients. Our method demonstrates competitive performance compared to current state-of-the-art methods. © 2024 Elsevier B.V.

Abstract This paper presents the continuous sweep quantifier, a smoothed adaptation of the median sweep quantifier. Previous research has shown that the median sweep quantifier is a good quantifier. However, it is not well understood why it performs well because it is hard to derive its theoretical properties. The continuous sweep quantifier is a modification of the median sweep quantifier that enables computing theoretical results. The continuous sweep quantifier 1) uses kernel estimates instead of the empirical distribution, 2) constructs decision boundaries instead of applying discrete decision rules, and 3) uses the mean instead of the median. We show that a simplified adaptation of the continuous sweep quantifier performs similarly to the median sweep quantifier in terms of bias and variance on the LeQua 2022 dataset. The continuous sweep quantifier can therefore be used to provide insights into the median sweep quantifier by computing theoretical expressions for bias and variance. © 2022 Copyright for this paper by

Unintended readmissions and reoperations within 30 and 90 days following adult spinal deformity surgery

Item Type Journal Article

Author S.-H. Seo

Author S.-J. Hyun

Author J.-K. Lee

Author K.-J. Kim

Abstract **OBJECTIVE** This study investigated the rates and etiologies of unintended readmissions and reoperations within 30 and 90 days after adult spinal deformity (ASD) surgery. The authors aimed to identify the risk factors for readmission and reoperation by analyzing patient demographic and surgical characteristics. **METHODS** This retrospective cohort study included 307 consecutive patients who

underwent surgery for ASD from 2012 to 2022 at a single academic institution. Data were collected on patient demographic characteristics, comorbidities, operative details, and postoperative complications. Chi-square and multivariable logistic regression models were used to identify the risk factors associated with 30- and 90-day readmissions and reoperations. **RESULTS** The mean $\pm$ SD age at surgery was 66.6 ± 10.5 years, and the majority (80.8%) of patients were female. The 30-day and 90-day readmission rates were 11.7% and 15.3%, respectively. Multivariable regression for 30-day readmissions revealed that length of hospital stay (LOS) after index surgery of > 20 days (OR 2.48) and surgical factors such as vertebral column resection (VCR) (OR 4.26) and pelvic fixation (OR 4.38) were risk factors. Other factors such as the American Society of Anesthesiologists Physical Status Classification System (ASA) class, prior spine surgery, and age were not associated with 30-day readmissions. Ninety-day readmission was associated with high ASA class (OR 2.37) and LOS > 20 days (OR 2.82). The 30- and 90-day reoperation rates were 7.8% and 10.1%, respectively. The variables associated with 30-day reoperations were intraoperative VCR (OR 3.34) and LOS > 20 days (OR 9.38). Ninety-day reoperations were associated with dural tears (OR 3.33) and LOS > 20 days (OR 3.68). **CONCLUSIONS** This study provides valuable insights into the incidence of unintended readmission and reoperation within 30 and 90 days after ASD surgery in an Asian population. By identifying the associated risk factors, healthcare providers can customize surgical strategies and optimize perioperative care to effectively mitigate these events. ©AANS 2025, except where prohibited by US copyright law.

UniOOD: A Unified Framework for Domain Generalization and Out-of-Distribution Detection in Time Series

Item Type Conference Paper

Author Y. Chen

Author W. Zheng

Author B.H. Gwee

Author Q. Cao

Author S.G. Razul

Author Z. Lin

Abstract Time series modeling faces two challenges: out-of-distribution (OOD) generalization to correctly classify sequences from distribution shift domains, and OOD detection to identify anomalous or previously unseen sequences. Existing methods usually address these separately, which limits their applicability in real-world scenarios. In this work, we propose UniOOD, a unified framework that tackles both challenges simultaneously. UniOOD divides sequences into patches, encodes each as a latent Gaussian distribution, and aggregates them into a sequence-level posterior via learned weighting. By aligning sequence posteriors with learnable class priors while maintaining inter-class separation, UniOOD learns representations that are both generalizable and discriminative. The distance between posteriors and class priors provides an intrinsic OOD score, enabling detection of unseen sequences without prior exposure. Experiments show UniOOD achieves state-of-the-art classification, strong OOD generalization, and effective OOD detection within a single unified model. © 2026 IEEE.

Universal Domain Adaptation for Simulation-Assisted SAR Target Recognition Based on Adversarial Uncertainty and Neighbor Relation

Item Type Journal Article

Author F. Gao

Author W. Ma

Author C. Yuan

Author J. Wang

Author J. Sun

Author A. Hussain

Abstract In the field of synthetic aperture radar (SAR) target recognition, leveraging computer-generated labeled simulated SAR data to aid in the recognition of unlabeled real SAR

data has garnered significant attention. However, the domain shift between the simulated and real domain contravenes the assumption of independent and identically distributed in deep learning (DL). Moreover, the categories of real SAR data may not align precisely with those of the simulated SAR data, and the prior knowledge of the label shift typically remains unavailable. To align the common category samples and identify target-private unknown category samples in the presence of both domain shift and potential label shift, we introduce a two-stage universal domain adaptation method for simulation-assisted SAR target recognition based on adversarial uncertainty and neighbor relation (AUNR). The proposed AUNR introduces Dirichlet distribution-based evidential DL, which not only performs classification tasks but also characterizes decision uncertainty, enabling the model to express the concept of 'Unknow.' In the first stage, alongside supervised learning, we leverage data augmentation-based contrastive learning to achieve robust feature representation. In the second stage, adversarial learning based on model and data uncertainty is employed to separate common and unknown class samples, and contrastive learning based on neighbor relation aligns samples in two domains according to their geometric relationships. To the best of our knowledge, this is the first study on UniDA for SAR target recognition. Experimental results demonstrate that our method outperforms previous State-of-the-Art methods in various label shift scenarios, which indicates the effectiveness of the proposed method. © 1965-2011 IEEE.

Universal Test-time Adaptation through Weight Ensembling, Diversity Weighting, and Prior Correction

Item Type Conference Paper

Author R.A. Marsden

Author M. Döbler

Author B. Yang

Abstract Since distribution shifts are likely to occur during testtime and can drastically decrease the model's performance, online test-time adaptation (TTA) continues to update the model after deployment, leveraging the current test data. Clearly, a method proposed for online TTA has to perform well for all kinds of environmental conditions. By introducing the variable factors domain non-stationarity and temporal correlation, we first unfold all practically relevant settings and define the entity as universal TTA. We want to highlight that this is the first work that covers such a broad spectrum, which is indispensable for the use in practice. To tackle the problem of universal TTA, we identify and highlight several challenges a self-training based method has to deal with: 1) model bias and the occurrence of trivial solutions when performing entropy minimization on varying sequence lengths with and without multiple domain shifts, 2) loss of generalization which exacerbates the adaptation to multiple domain shifts and the occurrence of catastrophic forgetting, and 3) performance degradation due to shifts in class prior. To prevent the model from becoming biased, we leverage a dataset and model-agnostic certainty and diversity weighting. In order to maintain generalization and prevent catastrophic forgetting, we propose to continually weightaverage the source and adapted model. To compensate for disparities in the class prior during test-time, we propose an adaptive prior correction scheme that reweights the model's predictions. We evaluate our approach, named ROID, on a wide range of settings, datasets, and models, setting new standards in the field of universal TTA. Unknown fault recognition and diagnosis under domain and class shift via neighborhood invariance learning and cross-domain mixup

Item Type Journal Article

Author Y. He

Author X. Kong

Abstract The application of transfer learning methods has effectively mitigated the challenges posed by operational condition variations in the fault diagnosis field. However, the assumption of label space consistency between the source and target domain has hindered the broader applicability of those methods. In industrial scenarios, the fault types across source and target domains often exhibit partial overlap, with potential emergence of novel, unknown fault classes in the target domain. This complex transfer scenario, characterized by both domain shift and label shift, defines the challenge of universal domain adaptation. To address this, we propose a universal domain adaptation diagnosis framework specifically designed for cross-domain identification of unknown faults unknown. The proposed method first employs the neighborhood invariance learning to optimize the separability of samples in the target domain. Then, a category prototype enhanced inter-domain mixup strategy generates pseudo-unknown samples, while an open-set classifier assigns the probabilities to unknown fault samples. Finally, a category consistency constraint is introduced to

refine the decision boundary between known and unknown fault categories. Multiple comparison experiments were conducted on the SDUST dataset to evaluate the effectiveness of the proposed method in these extreme transfer scenarios. The experimental results demonstrate that the method proposed in this manuscript achieves superior performance compared to state-of-the-art universal domain adaptation methods. © 2025 Elsevier Ltd

Unmanned Aerial Multi-Object Dynamic Frame Detection and Skipping Using Deep Learning on the Internet of Drones

Item Type Journal Article

Author U. Ahmed

Author J.C.-W. Lin

Author G. Srivastava

Abstract The Internet of Drones (IoD) has a revolutionary impact on monitoring and preserving the environment. Traffic regulations face enormous challenges due to rapid growth in the number of vehicles. In IoD, multiple-aerial-drone video sensing infrastructure can increase detected objects. However, the main difficulty lies in picture quality due to lighting conditions, the angle of view, and the physical structure of vehicles. This research mainly focuses on the development and deployment of a deep-learning-based system to analyze traffic congestion. The model uses multiple drone video feeds and vehicle information to detect, classify, and count a transport vehicle in a live traffic feed. The model is trained with a deep learning approach to first align the video frame and then detect the object in a top-down aerial drone video. The dynamic skipping method helps process a long video feed and accurately compares the video frame to the viewer, and then, using the standard vehicle query (i.e., make, model and year of manufacture), detect traffic scenarios in real time. The proposed model has many applications requiring a particular area to monitor real-time data analysis and drone routine tasks. © 2018 IEEE.

Unraveling the efficiency-equity trade-off in urban heat island mitigation by blue–green–grey space optimization in China

Item Type Journal Article**Author** Z. Liu

Abstract Rapid urbanization has shifted the urban climate management paradigm from passive expansion control to the active optimization of existing biophysical properties. However, conventional mitigation frameworks often overlook the physical interdependence of urban surfaces and the inequity inherent in cooling resource distribution. This study integrates interpretable machine learning to quantify seasonal thermal contributions and a novel 3D Convex Hull model to determine the physically constrained mitigation ceilings of Blue–Green–Grey (BGG) spaces across 199 major prefecture-level cities in China (2000–2024) at a 1-km spatial resolution. The proposed method achieved good random hold-out performance ($R^2 = 0.83$) and revealed a distinct spatiotemporal differentiation of cooling mechanisms: Green space is statistically associated with the largest share of model-attributed cooling and exhibits a clear phenological curve, especially in the ecologically restored Loess Plateau. Blue space provides a unique dual-seasonal thermal buffer, peaking in both summer and winter. Grey space contribution is largely radiation-dependent, becoming highly pronounced in summer. Overall, BGG optimization can achieve a local cooling capacity of 1.01–5.46 °C, with a critical efficiency-equity trade-off under various intervention scenarios. While maximizing cooling efficiency yields a superior mitigation capacity (2.23 °C), it exacerbates spatial inequality. Conversely, cooling footprint expansion (1.83 °C) enhances spatial equity by reducing the Gini index by 0.3. These findings provide practical support for climate-resilient urban development. © 2026 Elsevier B.V.

Abstract While Positive-Unlabeled (PU) learning is vital in many real-world scenarios, its application to graph data still remains under-explored. We unveil that a critical challenge for PU learning on graph lies on the edge heterophily, which directly violates the irreducibility assumption for Class-Prior Estimation (class prior is essential for building PU learning algorithms) and degenerates the latent label inference on unlabeled nodes during classifier training. In response to this challenge, we introduce a new method, named Graph PU Learning with Label Propagation Loss (GPL). Specifically, GPL considers learning from PU nodes along with an intermediate heterophily reduction, which helps mitigate the negative impact of the heterophilic structure. We formulate this procedure as a bilevel optimization that reduces heterophily in the inner loop and efficiently learns a classifier in the outer loop. Extensive experiments across a variety of datasets have shown that GPL significantly outperforms baseline methods, confirming its effectiveness and superiority. Copyright 2024 by the author(s)

Abstract Background White matter hyperintensities (WMH) are commonly detected on brain magnetic resonance imaging (MRI) scans of migraine patients, but their clinical relevance and underlying mechanisms remain uncertain. Objective To systematically review the relationship between WMH and migraine, focusing on prevalence, progression, and associations with clinical and demographic characteristics. Methods We conducted a systematic review of observational studies published between 1990 and May 2025, including adult patients with migraine (with or without aura) who underwent brain MRIs with at least 1.5T scanners. Data extraction was performed by two independent reviewers, with disagreements resolved by a third. Study quality was assessed using the Newcastle-Ottawa scale for observational studies. Results A total of 25 studies were included, comprising approximately 3,600 participants, of whom 1,725 had migraine. Most participants were women and reported age means or medians typically between 30 and 60 years. Frequently, WMHs were observed in

migraine patients, particularly in those with aura, longer disease duration, and higher headache frequency. No consistent association was found between WMH and comorbidities. Significant heterogeneity in imaging protocols, lesion quantification methods, and study design limited data comparability and precluded meta-analysis. Conclusion Migraine patients often present with WMHs, but their clinical significance remains unclear. Future studies should employ standardized MRI protocols, volumetric lesion quantification, and consistent migraine phenotyping to clarify its pathophysiological role in migraine and potential implications for diagnosis and management. © 2025 The Author(s).

Abstract In this work, we propose an unsupervised domain adaptation (UDA) framework for 3D volumetric lesion detection that adapts a detector trained on labeled FDG PET/CT to unlabeled PSMA PET/CT. Beyond covariate shift, cross tracer adaptation also exhibits label shift in both lesion size composition and the number of lesions per subject. We introduce self-training with two mechanisms that explicitly model and compensate for this label shift. First, we adaptively adjust the detection anchor shapes by re-estimating target domain box scales from selected pseudo labels and updating anchors with an exponential moving average. This increases positive anchor coverage for small PSMA lesions and stabilizes box regression. Second, instead of a fixed confidence threshold for pseudo-label selection, we allocate size bin-wise quotas according to the estimated target domain histogram over lesion volumes. The self-training alternates between supervised learning with prior-guided pseudo labeling on PSMA and supervised learning on labeled FDG. On AutoPET 2024, adapting from 501 labeled FDG studies to 36918 F-PSMA studies, the proposed method improves both AP and FROC over the source-only baseline and conventional self-training without label-shift mitigation, indicating that modeling target lesion prevalence and size composition is an effective path to robust cross-tracer detection. © 2026 IEEE.

Abstract During the onset of a natural or man-made crisis event, public often share relevant information for emergency services on social web platforms such as Twitter. However, filtering such relevant data in real-time at scale using social media mining is challenging due to the short noisy text, sparse availability of relevant data, and also, practical limitations in collecting large labeled data during an ongoing event. In this paper, we hypothesize that unsupervised domain adaptation through multi-task learning can be a useful framework to leverage data from past crisis events for training efficient information filtering models during the sudden onset of a new crisis. We present a novel method to classify relevant social posts during an ongoing crisis without seeing any new data from this event (fully unsupervised domain adaptation). Specifically, we construct a customized multi-task architecture with a multi-domain discriminator for crisis analytics: multi-task domain adversarial attention network (MT-DAAN). This model consists of dedicated attention layers for each task to provide model interpretability; critical for real-world applications. As deep networks struggle with sparse datasets, we show that this can be improved by sharing a base layer for multitask learning and domain adversarial training. The framework is validated with the public datasets of TREC incident streams that provide labeled Twitter posts (tweets) with relevant classes (Priority, Factoid, Sentiment) across 10 different crisis events such as floods and earthquakes. Evaluation of domain adaptation for crisis events is performed by choosing one target event as the test set and training on the rest. Our results show that the multi-task model outperformed its single-task counterpart. For the qualitative evaluation of

interpretability, we show that the attention layer can be used as a guide to explain the model predictions and empower emergency services for exploring accountability of the model, by showcasing the words in a tweet that are deemed important in the classification process. Finally, we show a practical implication of our work by providing a use-case for the COVID-19 pandemic. © 2020 IEEE.

Unsupervised Characterization of Temporal Dataset Shifts as an Early Indicator of AI Performance Variations: Evaluation Study Using the Medical Information Mart for Intensive Care-IV Dataset

Item Type Journal Article

Author D. Fernández-Narro

Author P. Ferri

Author A. Gutiérrez-Sacristán

Abstract Background: Reusing long-term data from electronic health records is essential for training reliable and effective health artificial intelligence (AI). However, intrinsic changes in health data distributions over time—known as dataset shifts, which include concept, covariate, and prior shifts—can compromise model performance, leading to model obsolescence and inaccurate decisions. Objective: In this study, we investigate whether unsupervised, model-agnostic characterization of temporal dataset shifts using data distribution analyses through Information Geometric Temporal (IGT) projections is an early indicator of potential AI performance variations before model development. Methods: Using the real-world Medical Information Mart for Intensive Care-IV (MIMIC-IV) electronic health record database, encompassing data from over 40,000 patients from 2008 to 2019, we characterized its inherent dataset shift patterns through an unsupervised approach using IGT projections and data temporal heatmaps. We trained and evaluated annually a set of random forests and gradient boosting models to predict in-hospital mortality. To assess the impact of shifts on model performance, we checked the association between the temporal clusters found in both IGT projections and the intertime embedding of model performances using the Fisher exact test. Results: Our results demonstrate a significant relationship between the unsupervised temporal shift patterns, specifically covariate and concept shifts, identified using the IGT projection method and the performance of the random forest and gradient boosting models ($P<.05$). We identified 2 primary temporal clusters that correspond to the periods before and after ICD-10 (International Statistical Classification of Diseases, Tenth Revision) implementation. The transition from ICD-9 (International Classification of Diseases, Ninth Revision) to ICD-10 was a major source of dataset shift, associated with a performance degradation. Conclusions: Unsupervised, model-agnostic characterization of temporal shifts via IGT projections can serve as a proactive monitoring tool to anticipate performance shifts in clinical AI models. By incorporating early shift detection into the development pipeline, we can enhance decision-making during the training and maintenance of these models. This approach paves the way for more robust, trustworthy, and self-adapting AI systems in health care. ©David Fernández-Narro, Pablo Ferri, Alba Gutiérrez-Sacristán, Juan M García-Gómez, Carlos Sáez. Unsupervised classification of biomedical abstracts using lexical association

Item Type Conference Paper**Author** J. Read**Author** J. Webster**Author** A.C. Fang

Abstract The task of text classification is the assignment of labels that describe texts' characteristics, such as topic, genre or sentiment. Supervised machine learning techniques such as Support Vector Machines or the simple but effective Naïve Bayes have been successfully applied to this task. However, it is not always practical to acquire a sufficient corpus of labelled examples to train these methods. For these cases we describe an unsupervised method for text classification based on two hypotheses. Firstly, we propose that the class of a document may be determined by calculating its constituent features' similarity with prototypical examples of each class. Secondly, we note the importance of class priors in Naïve Bayes classifiers, and hypothesize that class distributions might be estimated using the relative frequency of prototype words. Performing experiments on a corpus of biomedical abstracts with topic information derived from the Medical Subject Headings (MeSH), we investigate the characteristics of the method when used in conjunction with basic, linguistic and knowledge-based features, and find that the performance of the unsupervised method is approximately 80% that of Naïve Bayes. Our research is significant in that it highlights a candidate method with good potential for further improvement when training on unlabelled data. © 2010 by Jonathon Read, Jonathan Webster, and Alex Chengyu Fang.

Abstract Multi source domain adaptation has recently emerged as an effective approach for well logging lithology identification under cross well distribution shifts. However, most existing approaches are built on the assumption that all source domains are fully labeled. In practice, source wells may be only partially annotated due to limited expert resources and operational constraints. Such partial annotation often leads to degraded performance, especially when the available labels are inconsistent or incomplete across different source wells. To tackle these challenges, we propose SR2-MSDA, a semi-supervised multi-source domain adaptation framework. SR2-MSDA employs a dynamic source weighting strategy that adaptively adjusts source domain weights based on their proximity to the target in feature space, and leverages unlabeled source samples through a teacher-student consistency scheme. In addition, to mitigate label heterogeneity across domains, we propose modulating the adversarial loss by integrating the target class prior with a class level gating mechanism for each source sample. Experiments on real well log data from an eastern oilfield show that SR2-MSDA consistently improves Accuracy and Macro-F1 by 4%-6% over multi source domain adaptation methods that utilize only labeled source samples. © 2026 IEEE.

Editor Nishino K.

Abstract Due to the high transferability of features extracted from early layers (called local features), aligning marginal distributions of local features has achieved compelling results in unsupervised domain adaptive object detection. However, such marginal feature alignment suffers from the class label shift between source and target domains. Existing class label shift correction methods focus on image classification, and cannot be directly applied to object detection due to objects' co-occurrence. Meanwhile, one property of local features is that they have small receptive fields and can be easily mapped back to specific areas of input images. Therefore, to handle object co-occurrence scenarios, we propose to leverage this property to decompose the source feature maps and compute the source domain class distribution at the pixel level. The decomposition is based on each feature pixel's receptive field overlap with ground-truth bounding boxes. In the target domain, where no labels are available, we estimate this distribution using predicted bounding boxes and thus get the estimated class label shift between domains. This estimated shift is further used to re-weight source local features during the feature alignment. To the best of our knowledge, this is the first work trying to explicitly correct class label shift in unsupervised domain adaptive object detection. Experimental results demonstrate that this approach can systematically improve several recent domain adaptive object detectors, such as SW and HTCNet on benchmark datasets with different degrees of class label shift. © 2023, The Author(s), under exclusive license to Springer Nature Switzerland AG.

Abstract Purpose: Ki67 is a protein associated with tumor proliferation and metastasis in breast cancer and acts as an essential prognostic factor. Clinical work requires recognizing tumor regions on Ki67-stained whole-slide images (WSIs) before quantitation. Deep learning has the potential to provide assistance but largely relies on massive annotations and consumes a huge amount of time and energy. Hence, a novel tumor region recognition approach is proposed for more precise Ki67 quantification. Methods: An unsupervised domain adaptive method is proposed, which combines adversarial and self-training. The model trained on labeled hematoxylin and eosin (H&E) data and unlabeled Ki67 data can recognize tumor regions in Ki67 WSIs. Based on the UDA method, a Ki67 automated assisted quantification system is developed, which contains foreground segmentation, tumor region recognition, cell counting, and WSI-level score calculation. Results: The proposed UDA method achieves high performance in tumor region recognition and Ki67 quantification. The AUC reached 0.9915, 0.9352, and 0.9689 on the validation set and internal and external test sets, respectively, substantially exceeding baseline (0.9334, 0.9167, 0.9408) and rivaling the fully supervised method (0.9950, 0.9284, 0.9652). The evaluation of automated quantification on 148 WSIs illustrated statistical agreement with pathological reports. Conclusion: The model trained by the proposed method is capable of accurately recognizing Ki67 tumor regions. The proposed UDA method can be readily extended to other types of immunohistochemical staining images. The results of automated assisted quantification are accurate and interpretable to provide assistance to both junior and senior pathologists in their interpretation. © 2022, CARS.

Unsupervised extraction of flood-induced backscatter changes in SAR data using markov image modeling on irregular graphs

Item Type Conference Paper
Author S. Martinis
Author A. Twele
Author S. Voigt

Abstract The near real-time provision of precise information about flood dynamics from synthetic aperture radar (SAR) data is an essential task in disaster management. A novel tile-based parametric thresholding approach under the generalized Gaussian assumption is applied on normalized change index data to automatically solve the three-class change detection problem in large-size images with small class a priori probabilities. The thresholding result is used for the initialization of a hybrid Markov model which integrates scale-dependent and spatiocontextual information into the labeling process by combining hierarchical with noncausal Markov image modeling. Hierarchical maximum a posteriori (HMAP) estimation using the Markov chains in scale, originally developed on quadrees, is adapted to hierarchical irregular graphs. To reduce the computational effort of the iterative optimization process that is related to noncausal Markov models, a Markov random field (MRF) approach is defined, which is applied on a restricted region of the lowest level of the graph, selected according to the HMAP labeling result. The experiments that were performed on a bitemporal TerraSAR-X StripMap data set from South West England during and after a large-scale flooding in 2007 confirm the effectiveness of the proposed change detection method and show an increased classification accuracy of the hybrid MRF model in comparison to the sole application of the HMAP estimation. Additionally, the impact of the graph structure and the chosen model parameters on the labeling result as well as on the performance is discussed. © 2006 IEEE.

Abstract What sorts of structure might enable a learner to discover classes from unlabeled data? Traditional approaches rely on feature-space similarity and heroic assumptions on the data. In this paper, we introduce unsupervised learning under Latent Label Shift (LLS), where we have access to unlabeled data from multiple domains such that the label marginals $p_{\mathbf{y}}(\mathbf{y})$ can shift across domains but the class conditionals $p_{\mathbf{x}|\mathbf{y}}(\mathbf{x}|\mathbf{y})$ do not. This work instantiates a new principle for identifying classes: elements that shift together group together. For finite input spaces, we establish an isomorphism between LLS and topic modeling: inputs correspond to words, domains to documents, and labels to topics. Addressing continuous data, we prove that when each label's support contains a separable region, analogous to an anchor word, oracle access to $p_{\mathbf{d}}(\mathbf{d})$ suffices to identify $p_{\mathbf{y}}(\mathbf{y})$ and $p_{\mathbf{x}|\mathbf{y}}(\mathbf{x}|\mathbf{y})$ up to permutation. Thus motivated, we introduce a practical algorithm that leverages domain-discriminative models as follows: (i) push examples through domain discriminator $p_{\mathbf{d}}(\mathbf{d})$; (ii) discretize the data by clustering examples in $p_{\mathbf{d}}(\mathbf{d})$ space; (iii) perform non-negative matrix factorization on the discrete data; (iv) combine the recovered $p_{\mathbf{y}|\mathbf{d}}(\mathbf{y}|\mathbf{d})$ with the discriminator outputs $p_{\mathbf{d}}(\mathbf{d})$ to compute $p_{\mathbf{x}|\mathbf{y}}(\mathbf{x}|\mathbf{y})$ @ $\mathbf{d}$. With semi-synthetic experiments, we show that our algorithm can leverage domain information to improve upon competitive unsupervised classification methods. We reveal a failure mode of standard unsupervised classification methods when data-space similarity does not indicate true groupings, and show empirically that our method better handles this case. Our results establish a deep connection between distribution shift and topic modeling, opening promising lines for future work. © 2022 Neural information processing systems foundation. Unsupervised optimal deep transfer learning for classification under general conditional shift

Item Type Journal Article**Author** J. Lang**Author** Y. Liu

Abstract Classifiers trained on labeled source data may yield misleading results when applied to unlabeled target data drawn from a different distribution. Transfer learning can rectify this by transferring knowledge from source to target data, but its effectiveness frequently relies on stringent assumptions, such as label shift or strong separation conditions. We introduce a novel general conditional shift assumption, which encompasses label shift as a special case and facilitates the identifiability of both the target distribution and the shift function without requiring a separation condition. Our classifier is constructed by integrating deep neural networks (DNNs) and a pseudo-maximum likelihood approach. We establish asymptotic error bounds for our DNN-based classifier and estimators of the conditional probabilities (Formula presented) for source data and the target label distribution (Formula presented), in terms of the intrinsic dimension of (Formula presented). Notably, the excess risk of the proposed classifier achieves the optimal minimax rate, up to a logarithmic factor. Our method not only eliminates the need to estimate the shift function, but also alleviates the

curse of dimensionality when (Formula presented) exhibits a low-dimensional structure. Numerical simulations, along with an analysis of an Alzheimer's disease dataset, underscore its exceptional performance. © The Author(s) 2026. Updates on the OECD NEA Working Party on Scientific Issues and Uncertainty Analysis of Reactor Systems (WPRS)

Item Type Conference Paper

Author O. Buss

Author H. Ferroukhi

Author K. Ivanov

Abstract Under the guidance of the Nuclear Science Committee of the OECD Nuclear Energy Agency (NEA), the Working Party on Scientific Issues and Uncertainty Analysis of Reactor Systems (WPRS) deals with reactor physics, radiation transport and dosimetry, core thermal-hydraulics (T/H), fuel performance, and associated multi-physics aspects for present and future nuclear power systems. It studies the modelling and simulation (M&S) of reactor systems, along with verification, validation and uncertainty quantification (VVUQ). It acts as a platform for international collaboration sustaining a vibrant community of practice, fostering periodic and synergistic interactions among its participants. Main foci of the WPRS activities are recommendations and policy advice in its domain of expertise, international benchmarking activities, data preservation, and education. The WPRS runs 13 active benchmarks covering a wide variety of systems ranging from conventional reactor systems to advanced reactor designs, including micro- and small modular reactors (SMRs). Since PHYSOR 2022, three notable new activities have been launched: a multi-stage T/H code validation benchmark based on data measured at the High Temperature Test Facility (HTTF) at Oregon State University, US, a comprehensive lead fast reactor benchmark based on the ALFRED design, and a Task Force on Artificial Intelligence and Machine Learning (AI/ML) for Scientific Computing in Nuclear Engineering, which will evaluate the performance of AI/ML in multi-physics M&S of reactor systems. In the domain of data preservation WPRS is overseeing four database projects including the well-known International Handbook of Evaluated Reactor Physics Benchmark Experiments (IRPhE) Project with 169 different experimental series that were performed at 57 different nuclear facilities. Another significant project is the Shielding Integral Benchmark Archive and Database (SINBAD), which is pioneering the implementation of open source software methodologies into the benchmark database development. On the education side, WPRS has successfully organized the first International School on Simulation of Nuclear Reactor Systems (SINUS) this year. It delivered a hybrid, hands-on-training encompassing multi-physics simulations and associated uncertainty quantification methodologies. The article provides an overview of the WPRS activities emphasizing new activities that have been launched since PHYSOR 2022 and the international co-operation opportunities. © 2024 AMERICAN NUCLEAR SOCIETY. Upgrading Reliability in Molecular Property Prediction by Robust Quantification of Uncertainty from Machine Learning Models

Item Type Journal Article

Author A. Kötter

Author K. Singh

Author H. Matter

Author G. Hessler

Author C. Grebner

Abstract Reliable methods to quantify the predictive uncertainty of machine learning (ML) models can significantly increase the impact of molecular property prediction and are routinely used in applications like active learning and ML-guided property optimization. Poor predictive accuracy of ML models is often related to (i) regions of the chemical space, which are characterized by large property differences for structurally similar molecules, and (ii) a lack of representation of test molecules in the training data. Here, we analyze the relationship between these error sources and the predictive uncertainty of popular uncertainty quantification (UQ) methods on molecular activity data sets. We find that several UQ methods struggle to identify poorly predicted compounds in regions of steep structure–activity relationships (SAR). We also demonstrate that the evaluation scenario, as defined by data splitting into training and test sets, significantly impacts observed UQ performance. Based on

our findings we introduce a simple but strong and very robust method for UQ that offers significant improvements over previous approaches in several evaluation scenarios and demonstrate its usefulness in an exploratory active learning setting. © 2025 The Authors. Upper and Lower Tight Error Bounds for Feature Omission with an Extension to Context Reduction

Item Type Journal Article

Author R. Schluter

Author E. Beck

Author H. Ney

Abstract In this work, fundamental analytic results in the form of error bounds are presented that quantify the effect of feature omission and selection for pattern classification in general, as well as the effect of context reduction in string classification, like automatic speech recognition, printed/handwritten character recognition, or statistical machine translation. A general simulation framework is introduced that supports discovery and proof of error bounds, which lead to the error bounds presented here. Initially derived tight lower and upper bounds for feature omission are generalized to feature selection, followed by another extension to context reduction of string class priors (aka language models) in string classification. For string classification, the quantitative effect of string class prior context reduction on symbol-level Bayes error is presented. The tightness of the original feature omission bounds seems lost in this case, as further simulations indicate. However, combining both feature omission and context reduction, the tightness of the bounds is retained. A central result of this work is the proof of the existence, and the amount of a statistical threshold w.r.t. the introduction of additional features in general pattern classification, or the increase of context in string classification beyond which a decrease in Bayes error is guaranteed. © 1979-2012 IEEE.

Urban landfill site selection using AHP and SA W in GIS environment (case study: Kohkiluye-O-Boyer Ahmad Province, Iran)

Item Type Journal Article

Author H.R. Jafari

Author Y. Rafii

Author M. Ramezani Mehrian

Author H. Nasiri

Abstract Introduction: Environmental conservation and optimal utilization of natural resources, is considered as the requirements of sustainable development at all levels, including regional levels. Sanitary urban landfill like any other engineering project needs basic information and accurate planning. Today, geographic information system (GIS) is widely utilized in environmental planning and engineering problems. Selecting a suitable location for a landfill requires considering several factors. Thus, the necessity of using spatial information technology and its integration with other planning and management issues will be inevitable. Multi-criteria decision-making systems include models and methods that have been provided by different people to make the process of planning easier for planners. These systems gradually improve their performance by others. Analytical Hierarchy Process (AHP) and simple Additive weighting (SAW) are systems of multi-criteria decision making that have been used in this paper. Materials and Methods: Criteria to this case were selected based on existing resources and environmental principles. These criteria include: distance from city, main roads, faults, main waterways and villages, rainfall, slope, elevation, land cover and Geology. Based on the weight that was assigned to layers in each of the two methods 10 weighted layers were created using GIS. In the next step, constraint map of the burial areas was prepared. Finally, the prepared maps were incorporated and multiplied in constraint layers in GIS, according to acquisitive weights in both AHP and SAW. Fig. 1 shows this process simply. Results and Discussion: According to the results of this process and classifying output maps, the priorities of areas for landfill was identified in Arc GIS. Given that in this study, two models were used to compare the quality of the output map, it is normal that the results obtained from these two models are different. After combining layers and their integration with the constraint map, output maps (Figures 2 and 3) were prepared for each of the two methods. Final map were classified in five categories based on the current classification as follows: 1. Restrained 2. Relatively poor 3. Relatively good 4. Appropriate and 5. Perfect (Figure Presented) Due to differences in methods of weighting of criteria and alternatives, the outcomes of AHP and SAW are to some extent different. In AHP method, perfect, Appropriate, relatively good and relatively poor Priorities respectively are 19%, 18%, 2% and 1%. While in SAW, perfect, Appropriate and relatively poor Priorities respectively are 22%, 18% and 1%. The restriction in both methods was 59%. (Figure Presented) Conclusion: Pair-wise comparison is more appropriate for determining the weight than their direct

determination (SAW), because in the pair-wise comparisons (AHP) classes' weight for each criterion is obtained based on a class priority rather than all classes of the criterion, but this process is not done in the direct determination of weight (SAW). After the production of output layers by the two methods, can be concluded with a superficial analysis that the AHP model presented more conservative results than the SAW. Finally, it can be claimed that the integrated system of GIS and multi-criteria decision-making can be a useful tool for environmental planning.

Use of an improved high-throughput absolute abundance quantification method to characterize soil bacterial community and dynamics

Item Type Journal Article

Author L. Yang

Author J. Lou

Author H. Wang

Author L. Wu

Author J. Xu

Abstract High-throughput sequencing has dramatically expanded our understanding of bacterial communities based on the information of the species types and their relative abundances. Recently, researchers have also become aware of a deficiency in not considering the absolute abundance in this technique. Combining two or more different methods has typically been used to achieve absolute quantification of microbial communities. However, making a combination of different methods not

only is time-consuming but also involves potential uncertainty due to variations in the experimental conditions. To simplify the experimental procedure and improve the high-throughput absolute abundance quantification (HAAQ) of a soil bacterial community, we propose an HAAQ method that uses an internal standard strain (ISS) HAAQ-GFP to simultaneously obtain both the relative and absolute abundances in the soil bacterial community. The results showed that a soil bacterial community and its dynamics can be better characterized by the HAAQ method when the optimal concentrations of ISS HAAQ-GFP (105 to 107 cells g⁻¹) were used, and a 16S rRNA gene copy number adjustment was applied. Based on the HAAQ method, we first found that soil bacterial absolute abundances at the genus level fitted well to the partial log-normal distribution function, and most genera concentrations were in the range of 103.5 to 106.5 cells g⁻¹ in the test soils. Our case studies also indicated that more comprehensive descriptions of soil bacterial communities and their dynamics can be achieved by both the relative and absolute abundances than by the relative abundance alone. The improved HAAQ method can be potentially applied to other microbial ecological studies and to stimulating the development of quantitative bacterial ecology studies. © 2018 Elsevier B.V.

Use of ensemble based on GA for imbalance problem

Item Type Conference Paper

Author L. Cleofas

Author R.M. Valdovinos

Author V. García

Author R. Alejo

Abstract In real-world applications, it has been observed that class imbalance (significant differences in class prior probabilities) may produce an important deterioration of the classifier performance, in particular with patterns belonging to the less represented classes. One method to tackle this problem consists to resample the original training set, either by over-sampling the minority class and/or under-sampling the majority class. In this paper, we propose two ensemble models (using a modular neural network and the nearest neighbor rule) trained on datasets under-sampled with genetic algorithms. Experiments with real datasets demonstrate the effectiveness of the methodology here proposed. © 2009 Springer Berlin Heidelberg.

Editor Tung T.T.

Editor Xiping D.

Abstract This Salt-marsh site classification is an important scientific basis for the effective and sustainable management of salt-marsh in the coastal area. The main aim of this research is to use of salt-marsh site classification to select suitable mangrove species for mangrove forest development and reforestation in the coastal area of Thai Binh province. Quantification method and six indicators of salt-marsh site classification such as type of salt-marsh, current status of mangrove forest and salt-marsh, exposed time of mudflat, soil maturity, sand percentage, altitude of mudflat and mapping of salt-marsh site classification of Thai Binh province (Dong Long commune, Tien Hai district, Thai Binh province, the scale of 1/5,000). Planting techniques for *Kandelia obovata* Sheue, H.Y. Liu & J. Yong, and *Sonneratia caseolaris* (L.) Engl such as cutting the top bud at the early stage of planting, using 3 bamboo stakes to stabilize trees were used. Survival rate increased 27% after 3 years of planting compared with control. The growth of mangrove forests in the experiment formula is very different, especially the site type group is very convenient, convenient and difficult, the survival rate of the experiment formula in the field type is favorable and very convenient from 60-70% after 3 years of planting mangrove forests, while the difficulty in survival is 10-20%. The probability of accretion in the experimental models is very clear, in the site type group is very favorable after 36 months of mangroves planting from 9.1 to 10.0 cm, clearly higher than the control (3,9cm). In the site-wise group, the increase of accretion from 6.8 to 7.1 cm was significantly higher than control (3.0 cm). In the difficult site group, the average accretion volume in the

following 36 months of planting was 4.3-4.5 cm, clearly higher than the control (2.1 cm). © Springer Nature Singapore Pte Ltd. 2020.

Using a unified measure function for heuristics, discretization, and rule quality evaluation in Ant-Miner

Item Type Conference Paper

Author K.M. Salama

Author F.E.B. Otero

Abstract Ant-Miner is a classification rule discovery algorithm that is based on Ant Colony Optimization (ACO) metaheuristic. cAnt-Miner is the extended version of the algorithm that handles continuous attributes on-the-fly during the rule construction process, while μ Ant-Miner is an extension of the algorithm that selects the rule class prior to its construction, and utilizes multiple pheromone types, one for each permitted rule class. In this paper, we combine these two algorithms to derive a new approach for learning classification rules using ACO. The proposed approach is based on using the measure function for 1) computing

the heuristics for rule term selection, 2) a criteria for discretizing continuous attributes, and 3) evaluating the quality of the constructed rule for pheromone update as well. We explore the effect of using different measure functions for on the output model in terms of predictive accuracy and model size. Empirical evaluations found that hypothesis of different functions produce different results are acceptable according to Friedman's statistical test. © 2013 IEEE.

Using Adversarial Training to Improve Uncertainty Quantification

Item Type Journal Article

Author K. Huang

Author M. Xu

Author Y. Wang

Abstract The success of adversarial attack methods suggests a small input change may mislead a trained machine-learning model. For example, changing one pixel of an image may cause the trained model to misclassify this updated image. Uncertainty quantification is crucial for detecting misclassifications; hence, precise uncertainty quantification, meaning uncertainty estimates that closely align with prediction correctness, is essential. We assume that misclassified samples should exhibit high uncertainty while correctly classified samples should exhibit low uncertainty. To evaluate the performance of uncertainty quantification, we investigate the task of uncertainty-

based misclassification detection under adversarial attack conditions. Our findings suggest that existing uncertainty quantification methods are unable to accurately identify misclassified predictions resulting from adversarial attacks due to training issues. We propose a simple adversarial training strategy for improving uncertainty quantification. Our results show that adversarial training improves the reliability of uncertainty quantification by better aligning uncertainty with prediction correctness. Specifically, we observe consistent improvements in misclassification detection performance, measured by AUC-ROC and AUC-PR, across clean and adversarial samples. © 2020 IEEE.

Using Bayesian networks to clarify interpretation of exposure–response regression coefficients: blood lead–mortality association as an example

Item Type Journal Article

Author L.A. Cox

Abstract We examine how Bayesian network (BN) learning and analysis methods can help to meet several methodological challenges that arise in interpreting significant regression coefficients in exposure–response regression modeling. As a motivating example, we consider the challenge of interpreting positive regression coefficients for blood lead level (BLL) as a predictor of mortality risk for nonsmoking men. We first note that practices such as dichotomizing or categorizing continuous confounders (e.g. income), omitting potentially important socioeconomic confounders (e.g. education), and assuming specific parametric regression model forms leave unclear to what extent a positive regression coefficient reflects these modeling choices, rather than a direct dependence of mortality risk on exposure. Therefore, significant exposure–response coefficients in parametric regression models do not necessarily reveal the extent to which reducing exposure-related variables (e.g. BLL) alone, while leaving fixed other correlates of exposure and mortality risks (e.g. education, income, etc.) would reduce adverse outcome risks (e.g. mortality risks). We then consider how BN structure-learning and inference algorithms and nonparametric estimation methods (partial dependence plots) can be used to clarify dependencies between variables, variable selection, confounding, and quantification of joint effects of multiple factors on risk, including possible high-order interactions and nonlinearities. We conclude that these details must be carefully modeled to determine whether a data set provides evidence that exposure itself directly affects risks; and that BN and nonparametric effect estimation and uncertainty quantification methods can complement regression modeling and help to improve the scientific basis for risk management decisions and policy-making by addressing these issues. © 2020 Informa UK Limited, trading as Taylor & Francis Group.

Abstract Neuronal activity-dependent transcription directs molecular processes that regulate synaptic plasticity, brain circuit development, behavioral adaptation, and long-term memory. Single cell RNA-sequencing technologies (scRNAseq) are rapidly developing and allow for the interrogation of activity-dependent transcription at cellular resolution. Here, we present NEUROeSTIMator, a deep learning model that integrates transcriptomic signals to estimate neuronal activation in a way that we demonstrate is associated with Patch-seq electrophysiological features and that is robust against differences in species, cell type, and brain region. We demonstrate this method's ability to accurately detect neuronal activity in previously published studies of single cell activity-induced gene expression. Further, we applied our model in a spatial transcriptomic study to identify unique patterns of learning-induced activity across different brain regions in male mice. Altogether, our findings establish NEUROeSTIMator as a powerful and broadly applicable tool for measuring neuronal activation, whether as a critical covariate or a primary readout of interest. © 2024, This is a U.S. Government work and not under copyright protection in the US; foreign copyright protection may apply.

Abstract Atmospheric aerosol pollution, such as fine particulate matter (PM2.5) and inhalable particulate matter (PM10), is one of the most important environmental problems in China. To mitigate particulate air pollution, the Chinese government has been implementing a series of clean air actions. Here, we conducted a comprehensive analysis on surface air pollutants data obtained from the China air quality observation network using a random forest (RF) approach, to evaluate the impact of clean air actions on aerosol pollution from 2015 to 2022. Overall, the observed PM2.5 and PM10 showed evidently decreasing trends during 2015–2022 in each season, with the largest trends in winter. Based on the RF model analysis, we further quantified the

seasonal-dependent trends in PM_{2.5} and PM₁₀ concentrations driven by anthropogenic emissions over China, which were approximately -3.84 and -6.14 , -2.82 and -4.71 , -2.58 and -4.45 , and -2.77 and -4.06 $\mu\text{g m}^{-3} \text{ yr}^{-1}$ for winter, spring, summer, and autumn, respectively. Furthermore, anthropogenic emissions were estimated to contribute 34.44 and 54.98, 24.10 and 37.22, 23.48 and 36.20, and 21.04 and 30.69 $\mu\text{g m}^{-3}$ to declines in annual mean PM_{2.5} and PM₁₀ concentrations during the eight years in megacity clusters of eastern China for winter, spring, summer, and autumn, respectively. These seasonal-dependent trend analyses reveal the largest reduction in ambient aerosol pollution due to anthropogenic emission abatements during cold season and further demonstrate substantial effectiveness of the clean air actions for improvement in particulate air quality in China. Correlation analysis on PM_{2.5} with the major meteorological parameters and the RF model built-in feature importance suggested that a combination of high relative humidity, shallow boundary layer heights, and low wind speeds could promote wintertime aerosol pollution in short-time scales over northern China (e.g., the North China plain). © 2023 Elsevier Ltd

Abstract Water-soluble humic-like substances (HULISws) are a group of heterogeneous organic compounds in the atmosphere, greatly impacting climate change and human health. As the most significant biomass burning (BB) and fossil fuel burning polluted area in China, Northeast China Plain could generate more light absorbing HULISws to the atmosphere. In this work, daily fine particle (PM_{2.5}) samples were collected in Changchun, located in Northeast China Plain, from October 17th to November 29th, 2016, to investigate the potential sources of optical properties of HULISws. Here, the whole sampling period was divided into three sub-periods using the density of fire spots and the timeline of the central heating: the non-heating (October 17th to October 24th), early heating (October 25th to November 13th), and normal heating (November 14th to November 29th) periods. The mean mass concentrations of HULISws were 4.2 ± 1.2 , 8.6 ± 3.6 , and $2.4 \pm 1.3 \mu\text{g m}^{-3}$ during the non-heating, early heating, and normal heating periods, respectively. The positive matrix factorization (PMF) model results suggested that the contribution of primary BB, secondary BB, and fossil fuel burning emissions were 46%, 24%, and 19% during the non-heating period, 22%, 29%, and 17% during the early heating period, and 13%, 16%, and 50% during the normal heating period, respectively. Combining the PMF results with the random forest (RF) algorithm, the contribution of each source to the optical properties was quantified. Here, BB still dominated the optical properties of HULISws in Northeast China. During the study period, the primary BB and secondary BB contributed 25% and 34% in the light absorption coefficient (Abs),

22% and 33% in the mass absorption exponent (MAE), and 17% and 33% in the absorption Ångström exponent (AAE), respectively. Other sources like cooking and fossil combustion contributed 25% and 35% in Abs, 35% and 26% in MAE, and 16% and 33% in AAE, respectively. © 2022 Elsevier Ltd

Using machine learning to quantify structural MRI neurodegeneration patterns of Alzheimer's disease into dementia score: Independent validation on 8,834 images from ADNI, AIBL, OASIS, and MIRIAD databases

Item Type Journal Article**Author** K. Popuri**Author** D. Ma**Author** L. Wang**Author** M.F. Beg

Abstract Biomarkers for dementia of Alzheimer's type (DAT) are sought to facilitate accurate prediction of the disease onset, ideally predating the onset of cognitive deterioration. T1-weighted magnetic resonance imaging (MRI) is a commonly used neuroimaging modality for measuring brain structure in vivo, potentially providing information enabling the design of biomarkers for DAT. We propose a novel biomarker using structural MRI volume-based features to compute a similarity score for the individual's structural patterns relative to those observed in the DAT group. We employed ensemble-learning framework that combines structural features in most discriminative ROIs to create an aggregate measure of neurodegeneration in the brain. This classifier is trained on 423 stable normal control (NC) and 330 DAT subjects, where clinical diagnosis is likely to have the highest certainty. Independent validation on 8,834 unseen images from ADNI, AIBL, OASIS, and MIRIAD Alzheimer's disease (AD) databases showed promising potential to predict the development of DAT depending on the time-to-conversion (TTC). Classification performance on stable versus progressive mild cognitive impairment (MCI) groups achieved an AUC of 0.81 for TTC of 6 months and 0.73 for TTC of up to 7 years, achieving state-of-the-art results. The output score, indicating similarity to patterns seen in DAT, provides an intuitive measure of how closely the individual's brain features resemble the DAT group. This score can be used for assessing the presence of AD structural atrophy patterns in normal aging and MCI stages, as well as monitoring the progression of the individual's brain along with the disease course. © 2020 The Authors. Using machine learning to quantify the impacts of genetically modified crops on US midwest corn yields

Item Type Journal Article

Author P.M. Johnson

Author R. Bennartz

Author J.V. Camp

Abstract Global food security is becoming increasingly stressed by growing populations and climate change. To compensate for these stresses, crop yields must increase throughout the upcoming century. One of the more prominently featured solutions entails genetically modified crops, but their impacts on yields are contested. Here, we leverage machine learning techniques to examine the effects genetically modified crops have had on US corn yields. In particular, a principal components analysis conducted on US Midwest county yields reveals that the commercialization of genetically modified corn accentuated preexisting spatial disparities in production

and explains approximately 6–12% of the region's inter-county variation in yields from 1980 to 2015. Additionally, counterfactual yield trajectories predicted by Bayesian structural time series models using non-genetically modified crops as synthetic controls suggest that the adoption of this biotechnology amounted to an approximate 13% increase in overall US corn yields from 1996 to 2015. © 2019 Elsevier Ltd

Using Machine Learning to Quantify the Multimedia Risk Due to Fuzzing

Item Type Journal Article

Author G.S. Kashyap

Author K. Malik

Author S. Wazir

Author R. Khan

Abstract There have been considerable advancements in multimedia technologies over the past 5 years. It has been observed that state-of-the-art multimedia systems face three broad categories of challenges: (1) Dependency on continuous network connections, (2) Data-sharing applications & collaboration, and (3) Security issues. Among these,

security vulnerability poses a major threat to modern multimedia systems. Therefore, it is imperative to carefully investigate the security issues that can endanger wireless and mobile communications. At present, multimedia security research mainly focuses on wireless traffic monitoring, wireless system attacks, and wireless and mobile security. In this paper, we have used the network attack-type, “Reconnaissance”, which contains two types of malicious activities: (1) OS scanning, and (2) Fuzzing. The goal of this paper is to quantify multimedia security risks due to Fuzzing by using various types of machine learning models. The highest accuracy i.e., 96.8%, is obtained using the XGBoost classifier, which is good compared to the existing models present in the literature. This is the first paper, to the best of our knowledge, that uses machine learning methods to differentiate between benign and malignant Fuzzing attacks. © 2021, The Author(s), under exclusive licence to Springer Science+Business Media, LLC, part of Springer Nature.

Using Machine Learning to Quantify the Robustness of Network Controllability

Item Type Conference Paper

Author A. Dhiman

Author P. Sun

Author R. Kooij

Editor Renault E.

Editor Boumerdassi S.

Editor Mühlethaler P.

Abstract This paper presents machine learning based approximations for the minimum number of driver nodes needed for structural controllability of networks under link-based random and targeted attacks. We compare our approximations with existing analytical approximations and show that our machine learning based approximations significantly outperform the existing closed-form analytical approximations in case of both synthetic and real-world networks. Apart from targeted attacks based upon the removal of so-called critical links, we also propose analytical approximations for out-in degree-based attacks. © 2021, Springer Nature Switzerland AG.

Using photographs and deep neural networks to understand flowering phenology and diversity in mountain meadows

Item Type Journal Article

Author A. John

Author E.J. Theobald

Author N. Cristea

Author A. Tan

Author J. Hille Ris Lambers

Abstract Mountain meadows are an essential part of the alpine–subalpine ecosystem; they provide ecosystem services like pollination and are home to diverse plant communities. Changes in climate affect meadow ecology on multiple levels, for example, by altering growing season dynamics. Tracking the effects of climate change on meadow diversity through the impacts on individual species and overall growing season dynamics is critical to conservation efforts. Here, we explore how to combine crowd-sourced camera images with machine learning to quantify flowering species richness across a range of elevations in alpine meadows located in Mt. Rainier National Park, Washington, USA. We employed three machine-learning techniques (Mask R-CNN, RetinaNet and YOLOv5) to detect wildflower species in images taken during two flowering seasons. We demonstrate that deep learning techniques can detect multiple species, providing information on flowering richness in photographed meadows. The results indicate higher richness just above the tree line for most of the species, which is comparable with patterns found using field studies. We found that the two-stage detector Mask R-CNN was more accurate than single-stage detectors like RetinaNet and YOLO, with the Mask R-CNN network performing best overall with mean average precision (mAP) of 0.67 followed by RetinaNet (0.5) and YOLO (0.4). We found that across the methods using anchor box variations in multiples of 16 led to enhanced accuracy. We also show that detection is possible even when pictures are interspersed with complex backgrounds and are not in focus. We found differential detection rates depending on species abundance, with additional challenges related to similarity in flower characteristics, labeling errors and occlusion issues. Despite these potential biases and limitations in capturing flowering abundance and location-specific quantification, accuracy was notable considering the complexity of flower types and picture angles in this dataset. We, therefore, expect that this approach can be used to address many ecological questions that benefit from automated flower detection, including studies of flowering phenology and floral resources, and that this approach can, therefore, complement a wide range of ecological approaches (e.g., field observations, experiments, community science, etc.). In all, our study suggests that ecological metrics like floral richness can be efficiently monitored by combining machine learning with easily accessible publicly curated datasets (e.g., Flickr, iNaturalist). © 2024 The Authors. Using procrustes distance and shape space for Automatic Target Recognition

Item Type Journal Article

Author G.J. Meyer

Author S.C. Gustafson

Author G.D. Arnold

Abstract Equating objects based on shape similarity (for example scaled Euclidean transformations) is often desirable to solve the Automatic Target Recognition (ATR) problem. The Procrustes distance is a metric that captures the shape of an object independent of the following transformations: translation, rotation, and scale. The Procrustes metric assumes that all objects can be represented by a set of landmarks (i.e. points), that they have the same number of points, and that the points are ordered (i.e., the exact correspondence between the points is known from one object to the next). Although this correspondence is not known for many ATP, problems, computationally feasible methods for examining all possible combinations are being explored. Additionally, most objects can be mapped to a shape space where translation, rotation, and scaling are removed, and distances between object points in this space can then form another useful metric. To establish a decision boundary in any classification problem, it is essential to know the a priori probabilities in the appropriate space. This paper analyzes basic objects (triangles) in two-dimensional space to assess how a known distribution in Euclidean space maps to the shape space. Any triangles whose three coordinate points are uniformly distributed within a two-dimensional box transforms to a bivariate independent normal distribution with mean (0, 0) and standard deviations of 2 in Kendall shape space (two points of the triangle are mapped to (-1/2, 0) and (1/2, 0)). The Central Limit Theorem proves that the limit of sums of finite variance distributions approaches the normal distribution. This is a reasonable model of the relationship between the three Euclidean coordinates relative to the single Kendall shape space coordinate. This paper establishes the relationship

between different objects in the shape space and the Procrustes distance, which is an established shape metric, between these objects. Ignoring reflections (because it is a special case), the Procrustes distance is isometric to the shape space coordinates. This result demonstrates that both Kendall coordinates and Procrustes distance are useful features for ATR. © 2002 SPIE · 0277-786X/02/\$15.00.

Using samples with label noise for robust continual learning

Item Type Journal Article

Author H. Nie

Author S. Fan

Author Y. Liu

Author Q. Yao

Author Z. Wang

Abstract Recent studies have shown that effectively leveraging samples with label noise can enhance model robustness by uncovering more reliable feature patterns. While existing methods, such as label correction methods and loss correction techniques, have demonstrated success in utilizing noisy labels, they assume that noisy and clean samples (samples with correct annotations) share the same label space. However, this assumption does not hold in continual machine learning, where new categories and tasks emerge over time, leading to label shift problems that are specific to this setting. As a result, existing methods may struggle to accurately estimate the ground truth

labels for noisy samples in such dynamic environments, potentially exacerbating label noise and further degrading performance. To address this critical gap, we propose a Shift-Adaptive Noise Utilization (SANU) method, designed to transform samples with label noise into usable samples for continual learning. SANU introduces a novel source detection mechanism that identifies the appropriate label space for noisy samples, leveraging a meta-knowledge representation module to improve the generalization of the detection process. By re-annotating noisy samples through label guessing and label generation strategies, SANU adapts to label shifts, turning noisy data into useful inputs for training. Experimental results across three continual learning datasets demonstrate that SANU effectively mitigates the label shift problem, significantly enhancing model performance by utilizing re-annotated samples with label noise. © 2025

Abstract IMPORTANCE: Current Parkinson disease (PD) measures are subjective, rater-dependent, and assessed in clinic. Smartphones can measure PD features, yet no smartphone-derived rating score exists to assess motor symptom severity in real-world settings. OBJECTIVES: To develop an objective measure of PD severity and test construct validity by evaluating the ability of the measure to capture intraday symptom fluctuations, correlate with current standard PD outcome measures, and respond to dopaminergic therapy. DESIGN, SETTING, AND PARTICIPANTS: This observational study assessed individuals with PD who remotely completed 5 tasks (voice, finger tapping, gait, balance, and reaction time) on the smartphone application. We used a novel machine-learning-based approach to generate a mobile Parkinson disease score (mPDS) that objectively weighs features derived from each smartphone activity (eg, stride length from the gait activity) and is scaled from 0 to 100 (where higher scores indicate greater severity). Individuals with and without PD additionally completed standard in-person assessments of PD with smartphone assessments during a period of 6 months. MAIN OUTCOMES AND MEASURES: Ability of the mPDS to detect intraday symptom fluctuations, the correlation between the mPDS and standard measures, and the ability of the mPDS to respond to

dopaminergic medication. **RESULTS:** The mPDS was derived from 6148 smartphone activity assessments from 129 individuals (mean [SD] age, 58.7 [8.6] years; 56 [43.4%] women). Gait features contributed most to the total mPDS (33.4%). In addition, 23 individuals with PD (mean [SD] age, 64.6 [11.5] years; 11 [48%] women) and 17 without PD (mean [SD] age 54.2 [16.5] years; 12 [71%] women) completed in-clinic assessments. The mPDS detected symptom fluctuations with a mean (SD) intraday change of 13.9 (10.3) points on a scale of 0 to 100. The measure correlated well with the Movement Disorder Society Unified Parkinson Disease's Rating Scale total ($r = 0.81$; $P < .001$) and part III only ($r = 0.88$; $P < .001$), the Timed Up and Go assessment ($r = 0.72$; $P = .002$), and the Hoehn and Yahr stage ($r = 0.91$; $P < .001$). The mPDS improved by a mean (SD) of 16.3 (5.6) points in response to dopaminergic therapy. **CONCLUSIONS AND RELEVANCE:** Using a novel machine-learning approach, we created and demonstrated construct validity of an objective PD severity score derived from smartphone assessments. This score complements standard PD measures by providing frequent, objective, real-world assessments that could enhance clinical care and evaluation of novel therapeutics. © 2018 American Medical Association. Using statistical measures for feature ranking

Item Type Journal Article

Author E.G. Mansoori

Abstract Feature ranking is a fundamental preprocess for feature selection, before performing any data mining task. Essentially, when there are too many features in the problem, dimensionality reduction through discarding weak features is highly desirable. In this paper, we have developed an efficient feature ranking algorithm for selecting the more relevant features prior to derivation of classification predictors. Regardless the ranking criteria which rely on the training error of a predictor based on a feature, our approach is distance-based, employing only the statistical distribution of classes in each feature. It uses a scoring function as ranking criterion to evaluate the correlation measure between each feature and the classes. This function comprises three measures for each class: the statistical between-class distance, the interclass overlapping measure, and an estimate of class impurity. In order to compute the statistical parameters, used in these measures, a normalized form of histogram, obtained for each class, is employed as its a priori probability density. Since the proposed algorithm examines each feature individually, it provides a fast and cost-effective method for feature ranking. We have tested the effectiveness of our approach on some benchmark data sets with high dimensions. For this purpose, some top-ranked features are selected and are used in some rule-based classifiers as the target data mining task. Comparing with some popular feature ranking methods, the experimental results show that our approach has better performance as it can identify the more relevant features eventuate to lower classification error. © 2013 World Scientific Publishing Company.

Using topological constraints as context for the joint classification of image regions in a traffic environment

Item Type Conference Paper

Author G. Lorenz

Abstract This paper presents an approach using context knowledge in form of topological constraints to improve the classification result for an automated scene analysis. The approach consists of an initial segmentation, in which the image is divided into a set of disjoint regions based on their respective color values and a subsequent joint classification, where the generated image regions are assigned to object classes. The classification is performed according to extracted feature measurements and context knowledge about the spatial relationships between the different object classes. The classification task is formulated as an optimization problem using a maximum a posteriori estimation rule. The classification criteria are combined using the Bayesian theorem, where feature measurements and context are coded as conditional probability density and a priori probability, respectively. A Markov random field model is used to get an analytical expression for the symbolic context knowledge. Through its associated Gibbs distribution a systematic way for designing the appropriate functional form of context is found. The optimization task is solved by applying an evolutionary algorithm. Due to a problem-related formulation of the necessary operators this has been proven to be a very efficient search strategy. The performance of the presented approach is demonstrated on synthetic and real world images, showing typical scenarios of road traffic on motorways.

Abstract Existing work in scientific machine learning (SciML) has shown that data-driven learning of solution operators can provide a fast approximate alternative to classical numerical partial differential equation (PDE) solvers. Of these, Neural Operators (NOs) have emerged as particularly promising. We observe that several uncertainty quantification (UQ) methods for NOs fail for test inputs that are even moderately out-of-domain (OOD), even when the model approximates the

solution well for in-domain tasks. To address this limitation, we show that ensembling several NOs can identify high-error regions and provide good uncertainty estimates that are well-correlated with prediction errors. Based on this, we propose a cost-effective alternative, DIVERSENO, that mimics the properties of the ensemble by encouraging diverse predictions from its multiple heads in the last feed-forward layer. We then introduce OPERATOR-PROBCONSERV, a method that uses these well-calibrated UQ estimates within the PROBCONSERV framework to update the model. Our empirical results show that OPERATOR-PROBCONSERV enhances OOD model performance for a variety of challenging PDE problems and satisfies physical constraints such as conservation laws. Using unsupervised machine learning to quantify physical activity from accelerometry in a diverse and rapidly changing population

Item Type Journal Article

Author C.B. Thornton

Author N. Kolehmainen

Author K. Nazarpour

Abstract Accelerometers are widely used to measure physical activity behaviour, including in children. The traditional method for processing acceleration data uses cut points to define physical activity intensity, relying on calibration studies that relate the magnitude of acceleration to energy expenditure. However, these relationships do not generalise across diverse populations and hence they must be parametrised for each subpopulation (e.g., age groups) which is costly and makes studies across diverse populations and over time difficult. A data-driven approach that allows physical activity intensity states to emerge from the data, without relying on parameters derived from external populations, offers a new perspective on this problem and potentially improved results. We applied an unsupervised machine learning approach, namely a hidden semi-Markov model, to segment and cluster the raw accelerometer data recorded (using a waist-worn ActiGraph GT3X+) from 279 children (9–38 months old) with a diverse range of developmental abilities (measured using the Paediatric Evaluation of Disability Inventory–Computer Adaptive Testing measure). We benchmarked this analysis with the cut points approach, calculated using thresholds from the literature which had been validated using the same device and for a population which most closely matched ours. Time spent active as measured by this unsupervised approach correlated more strongly with PEDI-CAT measures of the child's mobility (R^2 : 0.51 vs 0.39), social-cognitive capacity (R^2 : 0.32 vs 0.20), responsibility (R^2 : 0.21 vs 0.13), daily activity (R^2 : 0.35 vs 0.24), and age (R^2 : 0.15 vs 0.1) than that measured using the cut points approach. Unsupervised machine learning offers the potential to provide a more sensitive, appropriate, and cost-effective approach to quantifying physical activity behaviour in diverse populations, compared to the current cut points approach. This, in turn, supports research that is more inclusive of diverse or rapidly changing populations. Copyright: © 2023 Thornton et al. Abstract Knee osteoarthritis (OA) affects 10% of the population over 55 years old, and is a major cause of work absence, early retirement, and joint replacement. The purpose of this study is to explore the possibility of using a recently proposed knee osteoarthritis biomarker and machine learning method to predict OA progression. The biomarker, named cartilage damage index (CDI), was extracted from 3D knee MR images by measuring representative locations. In total, the CDI measured 60 locations on the whole knee cartilage, including 18 from femur, 18 from tibia, and 24 from patella. The CDI values at these 60 locations in the baseline year were used as feature input to the artificial neural network (ANN). We trained two types of model to predict OA and OA severity change, respectively. The label of each sample was 'OA' or 'non-OA', based on the severity level in two years when training the model for OA prediction; and the label of each sample was 'change' or 'no-change' based on the severity level change in two years, when training the model for OA change prediction. Separate ANN models were trained for three OA severity measures, i.e., lateral Joint Space Narrow (JSN), medial JSN and Kellgren and Lawrence (KL) grade. Besides using all the 60 informative locations, we tested different combinations of CDI locations at sub-regions. The best prediction result achieved in this work was AUC (area under ROC curve) = 0.912, using the whole knee CDI (all 60 locations) to predict lateral JSN. Experiment results showed that CDI can be used

as a reliable cartilage quantification method and help to predict OA progression in two years. © 2018 IEEE.

Abstract Purpose To evaluate the predictive ability of a deep learning-based algorithm to determine long-term best-corrected distance visual acuity (BCVA) outcomes in neovascular age-related macular degeneration (nARMD) patients using baseline swept-source optical coherence tomography (SS-OCT) and OCT-angiography (OCT-A) data. Methods In this phase IV, retrospective, proof of concept, single center study, SS-OCT data from 17 previously treated nARMD eyes was used to assess retinal layer thicknesses, as well as quantify intraretinal fluid (IRF), subretinal fluid (SRF), and serous pigment epithelium detachments (PEDs) using a novel deep learning-based, macular fluid segmentation algorithm. Baseline OCT and OCT-A morphological features and fluid measurements were correlated using the Pearson correlation coefficient (PCC) to changes in BCVA from baseline to week 52. Results Total retinal fluid (IRF, SRF and PED) volume at baseline had the strongest correlation to improvement in BCVA at month 12 (PCC = 0.652, $p = 0.005$). Fluid was subsequently sub-categorized into IRF, SRF and PED, with PED volume having the next highest correlation (PCC = 0.648, $p = 0.005$) to BCVA improvement. Average total retinal thickness in isolation demonstrated poor correlation (PCC = 0.334, $p = 0.189$). When two features, mean choroidal neovascular membranes (CNVM) size and total fluid volume, were combined and correlated with visual outcomes, the highest correlation increased to PCC = 0.695 ($p = 0.002$). Conclusions In isolation, total fluid volume most closely correlates with change in BCVA values between baseline and week 52. In combination with complimentary information from OCT-A, an improvement in the linear correlation score was observed. Average total retinal thickness provided a lower correlation, and thus provides a lower predictive outcome than alternative metrics assessed. Clinically, a machine-learning approach to analyzing fluid metrics in combination with lesion size may provide an advantage in personalizing therapy and predicting BCVA outcomes at week 52. Utilizing 3D fast spin echo anatomical imaging to reduce the number of contrast preparations in T1ρ quantification of knee cartilage using learning-based methods

Item Type	Journal Article

Abstract	Purpose: To propose and evaluate an accelerated (Formula presented.) quantification method that combines (Formula presented.) -weighted fast spin echo (FSE) images and proton density (PD)-weighted anatomical FSE images, leveraging deep learning

models for (Formula presented.) mapping. The goal is to reduce scan time and facilitate integration into routine clinical workflows for osteoarthritis (OA) assessment. Methods: This retrospective study utilized MRI data from 40 participants (30 OA patients and 10 healthy volunteers). A volume of PD-weighted anatomical FSE images and a volume of (Formula presented.) -weighted images acquired at a non-zero spin-lock time were used as input to train deep learning models, including a 2D U-Net and a multi-layer perceptron (MLP). (Formula presented.) maps generated by these models were compared with ground truth maps derived from a traditional non-linear least squares (NLLS) fitting method using four (Formula presented.) -weighted images. Evaluation metrics included mean absolute error (MAE), mean absolute percentage error (MAPE), regional error (RE), and regional percentage error (RPE). Results: The best-performed deep learning models achieved RPEs below 5% across all evaluated scenarios. This performance was consistent even in reduced acquisition settings that included only one PD-weighted image and one (Formula presented.) -weighted image, where NLLS methods cannot be applied. Furthermore, the results were comparable to those obtained with NLLS when longer acquisitions with four (Formula presented.) -weighted images were used. Conclusion: The proposed approach enables efficient (Formula presented.) mapping using PD-weighted anatomical images, reducing scan time while maintaining clinical standards. This method has the potential to facilitate the integration of quantitative MRI techniques into routine clinical practice, benefiting OA diagnosis and monitoring. © 2025 The Author(s). Abstract Composite materials are increasingly being utilized in aerospace applications for their high stiffness and strength to weight ratios and fatigue resistance. However, defects in the composite may arise during cure (e.g. porosity, delamination, fiber waviness), and current technology only allows for post-cure evaluation (e.g. microscopy, ultrasonic inspection). A high-temperature ultrasonic scanning system was developed for deployment in an autoclave, which can detect porosity in composites during the cure process. This study focused on the implementation of machine learning techniques to help generate a model that can quantify porosity, in addition to detection and

localization that has previously been demonstrated. Two, six-hour-long experiments were conducted on curing of 762 mm × 305 mm (30 in. × 12 in.) composite panels with a [0/45/90/-45]_{4s} layup and varying regions of high and low pressure due to its tapered geometry in contact with a flat caul plate. The first experiment utilized a thick (12.7 mm) caul plate and the second utilized a thin (3.2 mm) caul plate. During experimentation, within the scan area (406 mm × 13 mm), data was recorded and stored for ultrasonic amplitude. Additional variables were measured or predicted including temperature, autoclave pressure, number of plies, slope of the composite panel surface with respect to the transducer, viscosity, and glass transition temperature. The pre-processed data was entered into the Regression Learner Application in MATLAB®,¹ and a rational quadratic Gaussian process regression (GPR) was chosen for the machine learning algorithm. The model was then trained on a larger data set to make it more robust and capable of predictions using a function callout. The result was a machine learning algorithm that can reliably quantify porosity in a composite panel during cure based on measured amplitude response and generate images for intuitive visualization. This tool can be further trained with more experimentation and potentially employed for real-time porosity detection and quantification of composite components during cure in an autoclave. Practical use of this technology is the potential to dynamically control processing parameters (e.g. autoclave pressure) in real-time to reduce the level of porosity within the laminate to acceptable limits (e.g. 2% by volume). © 2023 American Society for Nondestructive Testing.

Validated reverse transcription droplet digital PCR serves as a higher order method for absolute quantification of Potato virus Y strains

Item Type Journal Article

Author N. Mehle

Abstract RNA viruses have a great potential for high genetic variability and rapid evolution that is generated by mutation and recombination under selection pressure. This is also the case of Potato virus Y (PVY), which comprises a high diversity of different recombinant and non-recombinant strains. Consequently, it is hard to develop reverse transcription real-time quantitative PCR (RT-qPCR) with the same amplification efficiencies for all PVY strains which would enable their equilibrate quantification; this is specially needed in mixed infections and other studies of pathogenesis. To achieve this, we initially transferred the PVY universal RT-qPCR assay to a reverse transcription droplet digital PCR (RT-ddPCR) format. RT-ddPCR is an absolute quantification method, where a calibration curve is not needed, and it is less prone to inhibitors. The RT-ddPCR developed and validated in this study achieved a dynamic range of quantification over five orders of magnitude, and in terms of its sensitivity, it was comparable to, or even better than, RT-qPCR. RT-ddPCR showed lower measurement variability. We have shown that RT-ddPCR can be used as a reference tool for the evaluation of different RT-qPCR assays. In addition, it can be used for quantification of RNA based on in-house reference materials that can then be used as calibrators in diagnostic laboratories. © 2018, Springer-Verlag GmbH Germany, part of Springer Nature.

Abstract The assessment of polymorphonuclear leukocyte (PMN) proportions (%) of endometrial samples is the hallmark for subclinical endometritis (SCE) diagnosis. Yet, a non-biased, automated diagnostic method for assessing PMN% in endometrial cytology slides has not been validated so far. We aimed to validate a computer vision software based on deep machine learning to quantify the PMN% in endometrial cytology slides. Uterine cytobrush samples were collected from 116 postpartum Holstein cows. After sampling, each cytobrush was rolled onto three different slides. One slide was stained using Diff-Quick, while a second was stained using Naphthol (golden standard to stain PMN). One single observer evaluated the slides twice at different days under light microscopy. The last slide was stained with a fluorescent dye, and the PMN% were assessed twice by using a fluorescence microscope connected to a smartphone. Fluorescent images were analyzed via the Oculyze Monitoring Uterine Health (MUH) system, which uses a deep learning-based

algorithm to identify PMN. Substantial intra-method repeatabilities (via Spearman correlation) were found for Diff-Quick, Naphthol, and Oculyze MUH ($r = 0.67$ to 0.76). The intra-method agreements (via Kappa value) at $\geq 1\%$ PMN ($\kappa = 0.44$ to 0.47) were lower than at >5 ($\kappa = 0.69$ to 0.78) or $>10\%$ ($\kappa = 0.67$ to 0.85) PMN cut-offs. The inter-method repeatabilities (via Lin's correlation) were also substantial, and values between Diff-Quick and Oculyze MUH, Naphthol and Diff-Quick, and Naphthol and Oculyze MUH were 0.68 , 0.69 , and 0.77 , respectively. The agreements among evaluation methods at $\geq 1\%$ PMN were weak ($\kappa = 0.06$ to 0.28), while it increased at >5 ($\kappa = 0.48$ to 0.81) or $>10\%$ ($\kappa = 0.50$ to 0.65) PMN cut-offs. To conclude, deep learning-based algorithms in endometrial cytology are reliable and useful for simplifying and reducing the diagnosis bias of SCE in dairy cows. © 2022 Sadeghi et al. Abstract Introduction Dopamine transporter imaging with 123I-FP-CIT single photon emission computed tomography (SPECT) is helpful for the differential diagnosis between Parkinsonian syndrome (PS) and essential tremor (ET). Although visual assessment and time-consuming manual evaluation techniques are readily available, a fully objective and automated dopamine transporter quantification technique is always preferable, at least in research and follow-up investigations. Our aim was to develop a novel automated magnetic resonance imaging (MRI)-based evaluation technique of dopamine transporter SPECT images and to compare its diagnostic accuracy with those of the gold-standard visual grading and manual dopamine transporter binding quantification methods. Methods 123I-FP-CIT SPECT and MRI sessions were conducted in 33 patients with PS (15 men; mean age: 60.3 ± 9.7 years) and 15 patients with ET (8 men; mean age: 54.7 ± 16.3 years). Striatal dopamine transporter binding was visually classified by 2 independent experts as normal or abnormal grade I, II and III. Caudal and putaminal specific uptake ratios were calculated by both automated MRI-based and manual evaluation techniques. Results We found almost perfect agreement ($\kappa = 0.829$) between the visual scores by the 2 observers. The automated method showed strong correlation with the visual and manual evaluation techniques and its diagnostic accuracy (sensitivity = 97.0%; specificity = 93.3%) was also comparable to these methods. The automatically determined uptake parameters showed negative correlation with the clinical severity of parkinsonism. Based on ordinal regression modelling, the automated MRI-based method could reliably determine the visual grading scores. Conclusion The novel MRI-based evaluation of 123I-FP-CIT SPECT images is useful for the differentiation of PS from ET. © 2016 Elsevier Ltd

Validation of inertial sensing-based wearable device for tremor and bradykinesia quantification

Item Type Journal Article
Author H. Dai

Author G. Cai

Author Z. Lin

Author Z. Wang

Author Q. Ye

Abstract Neurologists judge the severity of Parkinsonian motor symptoms according to clinical scales, and their judgments exist inconsistent because of differences in clinical experience. Correspondingly, inertial sensing-based wearable devices (ISWDs) produce objective and standardized quantifications. However, ISWDs indirectly quantify symptoms by parametric modeling of angular velocities and linear accelerations and trained by the judgments of several neurologists through supervised learning algorithms. Hence, the ISWD outputs are biased along with the scores provided by neurologists. To investigate the effectiveness ISWDs for Parkinsonian symptoms quantification, technical verification and clinical validation of both tremor and bradykinesia quantification methods were carried out. A total of 45 Parkinson's disease patients and 30 healthy controls performed the tremor and finger-tapping tasks, which were tracked simultaneously by an ISWD and a 6-axis high-precision electromagnetic tracking system (EMTS). The Unified Parkinson's Disease Rating Scale (UPDRS) prescribed parameters obtained from the EMTS, which directly provides linear and rotational displacements, were compared with the scores provided by both the ISWD and seven neurologists. EMTS-based parameters were regarded as the ground truth and were employed to train several common machine learning (ML) algorithms, i.e., support vector machine (SVM), k-nearest neighbors (KNN), and random forest (RF) algorithms. Inconsistency among the scores provided by the neurologists was proven. Besides, the quantification performance (sensitivity, specificity, and accuracy) of the ISWD employed with ML algorithms were better than that of the neurologists. Furthermore, EMTS can be utilized to both modify the quantification algorithms of ISWDs and improve the assessment skills of young neurologists. © 2013 IEEE.

Validation of Information Products of Airborne Hyperspectral Imagery Processing

Item Type Journal Article

Author V.V. Kozoderov

Author T.V. Kondranin

Author E.V. Dmitriev

Author V.P. Kamentsev

Abstract Abstract: In regards to the problem of airborne hyperspectral imagery processing, most attention is paid to the construction of an automated classifier which implements computational procedures of recognizing forest vegetation of different species composition and age. The validation of the information products obtained as a result of processing the data of hyperspectral remote sensing is based on finding a maximum of a posteriori probability for selected classes of objects using the contemporary views of Markov random fields allowing a priori probabilities for each element of hyperspectral apparatus resolution to be calculated. The necessity of taking into account the noise component of the apparatus to enhance the accuracy of

solving the applied problems under study is shown. Examples of comparing the data of hyperspectral imagery processing with the data of ground-based forest inventory for a selected territory are demonstrated. © 2019, Pleiades Publishing, Ltd.

Author M. Courbariaux

Abstract Background : Wastewater-based epidemiology has been investigated as a very effective way of monitoring SARS-CoV-2 variants. This can be achieved through accurate lineage deconvolution of wastewater sequencing data. Variants Ratios from Pooled Sequencing (VaRaPS) is a Python package designed for this purpose, utilizing pooled sequencing data and lineage mutation profiles to estimate their proportions. Results : VaRaPS re-implements core algorithms from the literature, achieving significant improvements in computational speed and efficiency. Comparative analyzes with simulated and synthetic data sets demonstrate its superior performance in lineage prevalence estimation, underscored by its user-oriented design for broader accessibility. Conclusions : By improving speed and accuracy in SARS-CoV-2 variant analysis, VaRaPS offers valuable insights into viral evolution, supporting ongoing surveillance efforts in the post-pandemic landscape. © The Author(s) 2025.

Variations in Vegetation Cooling Efficiency Across 20 Major Cities Worldwide: The Interplay of Built-Up Fraction and Surface Properties

Item Type Journal Article

Author L. Hu

Author H. Neidhardt

Author A. Braun

Author V. Hochschild

Abstract Urban vegetation is widely regarded as a key strategy for mitigating urban heat, but its cooling performance is not constant and varies across climatic zones and urban structures. Most existing evidence derives from single-city or single-climate studies, leaving the differences in vegetation cooling with respect to building density and background climate insufficiently quantified globally. This study examined vegetation cooling efficiency (CE), defined as the absolute slope of the relationship between NDVI and normalized land surface temperature (LST), across 20 major cities spanning tropical, arid, temperate, and continental climate zones during 2000–2020. We combined city-level regression, built-up fraction stratification, and interpretable machine learning to quantify vegetation CE and its variation across climate and urban density gradients. CE varied roughly eightfold across cities (≈ 0.07 – 0.60), with the strongest responses in arid and continental cities such as Dubai and Almaty. Increasing built-up fraction systematically weakened the NDVI–LST relationship, turning near-neutral or slightly positive in the most compact temperate cores (80%–100% built-up). The machine learning model reproduced these patterns (out-of-sample $R^2 = 0.757$), identifying NDVI and evapotranspiration as dominant drivers. These findings indicate that vegetation cooling is strongly context-dependent, underscoring the need for climate-specific and morphology-based perspectives on urban greening rather than generalized evaluations. © 2026 by the authors.

Variogram Roughness Method for Casting Surface Characterization

Item Type Journal Article

Author D.W. Schimpf

Author F.E. Peters

Abstract Casting surface specifications are set based on aesthetics, functionality, or a combination of both. To classify casting surfaces, visual inspections are performed by an operator who compares the casting surface to pictures or comparator plates (e.g., metal, plastic) that represent a certain roughness level. This inspection process is highly subjective, and disagreements arise on the acceptance of a casting between the casting producer and buyer. To minimize these disagreements and use developments in 3D scanning, this study aims to develop a digital surface characterization method. The method developed and implemented in this study utilizes underlying geometry estimation, abnormality detection, and a new roughness characterization formula based on a variogram to determine a surface roughness value. Tests were done to compare the new roughness characterization formula with existing quantification methods (i.e., Sa, Sq) and to compare the results of the method with human operators. The tests indicated that the variogram roughness was able to differentiate between the roughness levels of the current surface roughness standards GAR-C9 and SCRATA. In addition, the results are repeatable as well as reproducible and agree with operator judgment based on a ranking comparison between the operator and the digital method. Overall, the digital surface roughness method has the potential to improve the communication between casting suppliers and designers and make the surface roughness classification more reliable and repeatable. © 2020, American Foundry Society.

Vehicle classification and lane categorization

Item Type Conference Paper

Author S. Ramesh

Author V. Upadhyaya

Abstract This research was carried out in order to use image processing techniques to detect, track, classify, and count vehicles in a real-time traffic video. Additionally this research also focuses on occlusion detection and handling, which involves detecting and handling the states when one vehicle superimposes the other or when two superimposed vehicles split, and lane categorization i.e. dividing the vehicles in the moving traffic scene into their corresponding lanes of the road in which they are travelling in. The challenge taken up was to achieve all this using basic image processing techniques and algorithms and not compromise on the desired output, most importantly keeping the single frame processing time less and the speed of processed video playback to be comparable to that real-time video playback speeds. It is to note that all of the above is achieved through the techniques demonstrated in this research. The process cycle followed from frame extraction to the final classification of vehicles involves algorithms that are all highly region based and do the necessary processing only on the region of interest, only as and when required. Thus saving processing power and time. The final results obtained could easily be molded to use in any application in surveillance, traffic monitoring etc. by just adding the required decision-making statements in it. © 2016 IEEE.

Vehicle Type Classification and Counting Using YOLOv4 Algorithm

Item Type Conference Paper

Author S.I.I.C. Imperial

Author A.L.L. Lucas

Author M.V. Caya

Abstract The study implements a system that detects, classify and count vehicles based on their body type. Classifying and counting has proven to be beneficial when monitoring and managing traffics. However, there are few of studies that focuses on classifying and counting vehicles based on their car types. Implementing the YOLOv4 for classification and counting for the car types coupe, pickup, sedan, sports utility vehicle (SUV) and van, obtained an accuracy of 92.13% for

classification and 89.14% for counting. The system was able to successfully classify and count vehicles based on their car type under one system compared to other system that only counts vehicles without classifying the car types. © 2022 IEEE.

Abstract Conformal Prediction (CP) is a popular uncertainty quantification method that provides distribution-free, statistically valid prediction sets, assuming that training and test data are exchangeable. In such a case, CP's prediction sets are guaranteed to cover the (unknown) true test output with a user-specified probability. Nevertheless, this guarantee is violated when the data is subjected to adversarial attacks, which often result in a significant loss of coverage. Recently, several approaches have been put forward to recover CP guarantees in this setting. These approaches leverage variations of randomised smoothing to produce conservative sets which account for the effect of the adversarial perturbations. They are, however, limited in that they only support ℓ_2 -bounded perturbations and classification tasks. This paper introduces VRCP (Verifiably Robust Conformal Prediction), a new framework that leverages recent neural network verification methods to recover coverage guarantees under adversarial attacks. Our VRCP method is the first to support perturbations bounded by arbitrary norms including ℓ_1 , ℓ_2 , and ℓ_∞ , as well as regression tasks. We evaluate and compare our approach on image classification tasks (CIFAR10, CIFAR100, and TinyImageNet) and regression tasks for deep reinforcement learning environments. In every case, VRCP achieves above nominal coverage and yields significantly more efficient and informative prediction regions than the SotA. © 2024 Neural information processing systems foundation. Vertical and horizontal approaches to the making of racial statistics in Britain

Item Type Journal Article

Author L. Brown

Abstract ABSTRACT: The release of data from the 2011 census fuelled a media storm over Britain's ethnic and immigrant composition, while at the same time a much less visible series of public debates developed over the scope, organization and purpose of government information-gathering centred on how the existing census could be replaced with 'Big data'. It is therefore particularly timely to explore the political choices, ontological shifts and statistical challenges shaping the array of enumeration projects that have developed in contemporary Britain to identify, classify, and count immigrants and their descendants. This article analyses the relationships between holistic (horizontal) and single-purpose (vertical) approaches to racial statistics, and how these were affected by the standardizations of classification in 1962 and 1991. A range of state archives and contemporary accounts are used to examine the material practices and organizational tensions that fuelled the divergence, transfer and interaction of these attempts at racial legibility. © 2016 Informa UK Limited, trading as Taylor & Francis Group.

Vertically transmitted bacterivorous nematodes are consistent nest inhabitants in the Azteca-Cecropia ant-plant mutualism

Item Type Journal Article

Author V. Barrajon-Santos

Author W. Sudhaus

Author B. Hausmann

Author D. Woebken

Author V.E. Mayer

Abstract Nematodes play key roles in natural and agricultural ecosystems. They contribute to organic matter transformation and the stability of soil food webs. Beyond their free-living forms, many nematode lineages have evolved in close associations with insects, ranging from mutualistic and commensal to parasitic interactions. Recent studies have revealed that nematodes are common in tropical ant-plant mutualisms and are particularly relevant in ant-made organic matter piles, or “patches”, within ant nests. To investigate nematode community dynamics during ant colony growth and their consistency across closely related ant species, we analysed patches from 65 ant colonies of the Azteca-Cecropia ant-plant mutualism using 18S rRNA metabarcoding combined with morphology-based quantification methods. Bacterivorous nematodes from the order Rhabditida were present in all samples, regardless of the ant or plant species and the colony developmental stage. Members of Tylenchida and Dorylaimida were also detected, though sporadically. Our results support the previously proposed vertical transmission of bacterivorous nematodes from mother to daughter colonies as well as horizontal transmission among patches within the same ant colony. Moreover, nematode community composition remained stable throughout colony development but varied between ant species. These findings demonstrate that nematodes constitute a persistent and functionally important component of this ant-plant mutualism. © The Author(s) 2026.

Video frames text detection through Bayesian classification and boundary growing method

Item Type Conference Paper

Author A. Nancy

Author D. Jayapriya

Abstract Text detection in natural scene images is important for content-based image analysis. It consists of different component analysis for text detection video frames. Multioriented text detection in video frames is one of the text detection in videos frames. Multi-oriented text detection is not easy as detection of captions or graphics which is usually appears in horizontal direction and has high contrast compared to its background. Multi-oriented text detection generally refers to scene text that makes text detection more challenging. Therefore conventional text detection may not give good results for multi-oriented video frames text detection. Hence, in this paper, we present a new enhancement method that includes the product of Laplacian and Sobel operations to enhance text pixels in videos. To classify true text pixels, we propose a Bayesian classifier without assuming a priori probability about the input frame but estimating it based on three probable matrices. Three different ways of clustering are performed on the output of the enhancement method to obtain the three probable matrices. Text candidates are obtained by intersecting the output of the Bayesian classifier with the Canny edge map of the input frame. The robustness of the methods are analyzed our own datasets under different video frames. Finally, it coarse-to-fine detection locates text regions efficiently. © 2014 IEEE.

Visible and near-infrared spectroscopy coupled with machine learning to quantify oxalate-extractable Al and Fe and identify andic soil properties for Japanese forest soils

Item Type Journal Article

Author S. Ishizuka

Author A. Imaiya

Author Y. Sakai

Author N. Yamashita

Abstract The combined content of oxalate-extractable aluminum (Alo) and 1/2 oxalate-extractable iron (Feo), expressed as $Alo + 1/2Feo$, is a key factor for identifying andic soil properties. Specifically, a value of ≥ 20 g kg⁻¹ for this variable is needed for andic soil properties in soils with less glass content. In this study, we thus developed a model to estimate the Alo and Feo contents in soils using visible and near-infrared spectroscopy coupled with machine learning. We evaluated the performance of three algorithms, namely partial least square regression, random forest (RF), and convolutional neural network (CNN). The CNN model outperformed the other models in estimating the Alo ($R^2 = 0.921$) and Feo ($R^2 = 0.723$) contents, with mean absolute errors of 2.3 and 2.0 g kg⁻¹ for Alo and Feo, respectively. In evaluating

whether the $\text{Al}_0 + 1/2\text{Fe}_0$ content of 2245 soil samples was $\geq 20 \text{ g kg}^{-1}$, the RF and CNN models produced only 124 and 88 misclassifications, respectively. Our method can serve as a time-efficient and chemical-free approach for identifying andic soil properties. © 2026 Japanese Society of Soil Science and Plant Nutrition.

Abstract The field of Vision-based Structural Health Monitoring (SHM) utilizes computer vision (CV), imaging techniques, and machine learning to quantify the integrity of structures. This survey sheds light on this field presenting an overview over

key techniques and advancements. In particular the survey presents classical image processing, digital image correlation (DIC), 3D modeling, and deep learning methods. Edge detection, thresholding, and segmentation can be considered as the classical damage identification tools, whereas DIC provides accurate deformation and strain measurements. Recent advancements in 3D modeling and deep learning have further boosted the efficiency and accuracy of crack detection, structural evaluation, and monitoring. Advanced deep learning methods such as convolutional neural networks (CNNs) and transfer learning (TL) have proven their effectiveness in automating crack detection and segmentation tasks under challenging and noisy conditions. This survey outlines strengths, weaknesses, and applicability to SHM with a view to transforming SHM into a non-contact, inexpensive, and fully automated monitoring system. © 2025 IEEE.

Visualization and quantification of coral reef soundscapes using
CoralSoundExplorer software

Item Type Journal Article**Author** L. Minier**Author** J. Rouch**Author** B. Sabbagh**Author** F. Bertucci**Author** E. Parmentier**Author** D. Lecchini**Author** F. Sèbe**Author** N. Mathevon**Author** R. Emonet

Abstract Despite hosting some of the highest concentrations of biodiversity and providing invaluable goods and services in the oceans, coral reefs are under threat from global change and other local human impacts. Changes in living ecosystems often induce changes in their acoustic characteristics, but despite recent efforts in passive acoustic monitoring of coral reefs, rapid measurement and identification of changes in their soundscapes remains a challenge. Here we present the new open-source software CoralSoundExplorer, which is designed to study and monitor coral reef soundscapes. CoralSoundExplorer uses machine learning approaches and is designed to eliminate the need to extract conventional acoustic indices. To demonstrate CoralSoundExplorer's functionalities, we use and analyze a set of recordings from three coral reef sites, each with different purposes (undisturbed site, tourist site and boat site), located on the island of Bora-Bora in French Polynesia. We explain the CoralSoundExplorer analysis workflow, from raw sounds to ecological results, detailing and justifying each processing step. We detail the software settings, the graphical representations used for visual exploration of soundscapes and their temporal dynamics, along with the analysis methods and metrics proposed. We demonstrate that CoralSoundExplorer is a powerful tool for identifying disturbances affecting coral reef soundscapes, combining visualizations of the spatio-temporal distribution of sound recordings with new quantification methods to characterize soundscapes at different temporal scales. © 2025 Minier et al. Wafer Pattern Counting, Detection and Classification Based on Encoder-Decoder CNN Structure

Item Type Conference Paper

Author Y. Lin

Abstract This paper designs an automatic wafer pattern counting pipeline based on a convolutional neural network (CNN) based structure, also called the WPCCNN network pipeline. The study will utilize deep learning algorithms to detect, binary classify and count wafer patterns. In the sample dataset, over two hundred wafers have been scanned by industrial computed tomography, containing 11 different patterns for the dataset images. Each image includes three processed steps. Moreover, it utilizes the lightweight CNN structure to demonstrate detection, classification, and estimated counting [1, 3]. Besides, the study also uses encoder and decoder structure on the CNN algorithm to obtain the closest expected output. Compared to traditional object counting methods, such as localization and density estimation, using this new method to count objects will be more accurate, faster, and more accessible [1-3]. The experiment results indicate that our algorithm is highly accurate with the paring between the original patterns and the labeled markers. The average counting accuracy is 99.6% in a single wafer. © 2022 IEEE.

Abstract Gradient boosting is a sequential ensemble method that fits a new weaker learner to pseudo residuals at each iteration. We propose Wasserstein gradient boosting, a novel extension of gradient boosting, which fits a new weak learner to alternative pseudo residuals that are Wasserstein gradients of loss functionals of probability distributions assigned at each input. It solves distribution-valued supervised learning, where the output values of the training dataset are probability distributions. In classification and regression, a model typically returns, for each input, a point estimate of a parameter of a noise distribution specified for a response variable, such as the class probability parameter of a categorical distribution specified for a response label. A main application of Wasserstein gradient boosting in this paper is tree-based evidential learning, which returns a distributional estimate of the response parameter for each input. We empirically demonstrate the competitive performance of the probabilistic prediction by Wasserstein gradient boosting in comparison with existing uncertainty quantification methods. © 2024 Neural information processing systems foundation. Watershed segmentation for vehicle classification and counting

Item Type Journal Article

Author P. Abinaya

Author K.S. Ravichandran

Author B. Santhi

Abstract A robust video based system for the traffic surveillance system on the highway for vehicle detection, vehicle classification and counting for effective traffic analysis using only a single standard camera. The key goal of the proposed work is to successfully detect, track, classify and count the vehicle in partial occlusion and

connected together by shadow on the highways. Marker-controlled watershed segmentation method is initially used for the extraction of the foreground regions from the highway scene. For tracking Gabor filter is applied which is used to measure vehicle path in video sequences. For effective vehicle classification support vector machine is utilized. An experiment result shows the considerable performance of watershed segmentation in vehicle detection in the occluded and connected together by shadow in the highways environment.

Wave condition prediction and uncertainty quantification based on SG-MCMC and deep learning model

Item Type Journal Article

Author M. Yu

Author Z. Wang

Author W. Lu

Author D. Song

Abstract Deep learning methods have increasingly gained popularity in wave prediction; however, previous works predominantly focused on point estimates without quantifying the uncertainty of predictions. In certain scenarios, generating probabilistic forecasts with credible intervals is crucial for vessel navigation planning and marine infrastructure construction, etc. Therefore, this paper attempts to conduct a benchmark study on wave prediction uncertainty from both frequentist and Bayesian perspectives. A wave prediction model based on the ConvLSTM combined with various uncertainty quantification methods has been established, and a unified

evaluation framework has been constructed using statistical decision theory. We utilized the fifth-generation atmospheric reanalysis dataset (ERA5) from the European Centre for Medium-Range Weather Forecasts as experimental data, employing key wave parameters (significant wave height, mean wave period, and mean wave direction) for model training and testing. Through extensive repeated experiments, we found that Bayesian methods generally provide more accurate average predictions, with the SG-MCMC method performing the best, achieving RMSE values of 0.37 m and 0.49 s for HS and TM at the 24-hour prediction, respectively, and CC values of 93.65 % and 90.65 %. On the other hand, confidence intervals obtained from frequentist methods offer broader coverage for data variations, with the MIS regression method performing the best, yielding the lowest MIS scores of only 2.92 m and 1.93 s for HS and TM at the 24-hour prediction, respectively. Indeed, this result underscores a limitation of current methods: the confidence intervals do not adequately reflect the accuracy of the predictions. In contrast, the SG-MCMC method demonstrates superior performance by excelling in both mean prediction and confidence limits. © 2025 Elsevier Ltd

Weakly supervised classification of objects in images using soft random forests

Item Type Conference Paper

Author R. Lefort

Author R. Fablet

Author J.-M. Boucher

Abstract The development of robust classification model is among the important issues in computer vision. This paper deals with weakly supervised learning that generalizes the supervised and semi-supervised learning. In weakly supervised learning training data are given as the priors of each class for each sample. We first propose a weakly supervised strategy for learning soft decision trees. Besides, the introduction of class priors for training samples instead of hard class labels makes natural the formulation of an iterative learning procedure. We report experiments for UCI object recognition datasets. These experiments show that recognition performance close to the supervised learning can be expected using the propose framework. Besides, an application to semi-supervised learning, which can be regarded as a particular case of weakly supervised learning, further demonstrates the pertinence of the contribution. We further discuss the relevance of weakly supervised learning for computer vision applications. © 2010 Springer-Verlag.

Abstract Fully supervised deep models have shown promising performance for many medical segmentation tasks. Still, the deployment of these tools in clinics is limited by the very time-consuming collection of manually expert-annotated data. Moreover, most of the state-of-the-art models have been trained and validated on moderately homogeneous datasets. It is known that deep learning methods are often greatly degraded by domain or label shifts and are yet to be built in such a way as to be robust to unseen data or label distributions. In the clinical setting, this problematic is particularly relevant as the deployment institutions may have different scanners or acquisition protocols than those from which the data has been collected to train the model. In this work, we propose to address these two challenges on the detection of clinically significant prostate cancer (csPCa) from bi-parametric MRI. We evaluate the method proposed by (Kervadec et al., 2018), which introduces a size constraint loss to produce fine semantic cancer lesions segmentations from weak circle scribbles annotations. Performance of the model is based on two public (PI-CAI and Prostate158) and one private databases. First, we show that the model achieves on-par performance with strong fully supervised baseline models, both on in-distribution validation data and unseen test images. Second, we observe a performance decrease for both fully supervised and weakly supervised models when tested on unseen data domains. This confirms the crucial need for efficient domain adaptation methods if deep learning models are aimed to be deployed in a clinical environment. Finally, we show that ensemble predictions from multiple trainings increase generalization performance. © 2024 CC-BY 4.0, R. Trombetta, O. Rouvière & C. Lartizien.

Abstract Reliable uncertainty quantification (UQ) is crucial for deploying deep learning models in safety-critical domains such as medical imaging. Existing post hoc UQ methods either rely on multi-pass inference or suffer from limited expressiveness due to their dependence on final-layer embeddings. In this work, we propose evidential meta model, a lightweight post-hoc framework that enhances Dirichlet evidential modeling by extracting features from multiple layers of a frozen classifier. This multilayer strategy enriches the metamodel input with both low-level textures and high-level semantics, enabling more accurate modeling of aleatoric and epistemic uncertainty. To further boost epistemic fidelity, we incorporate Max-WEnt regularization, which maximizes the entropy of learnable scaling weights applied within the meta-model. This promotes internal hypothesis diversity without modifying the base network or incurring test-time overhead. Across seven benchmarks including medical datasets (BACH, DIV2K, HAM10000, BreakHis) and natural image tasks (SVHN, Fashion-MNIST, ImageNet-C) our evidential metamodel consistently improves AUROC and calibration over both the base model and prior post-hoc UQ methods. Ablation studies confirm the complementary benefits of multilayer features and Max-WEnt. Our approach offers a robust and efficient solution for trustworthy AI in clinical and other high stakes settings. © 2026, Association for the Advancement of Artificial Intelligence (www.aaai.org). Weight-height relationships and central obesity in 7-year-old to 10-year-old Polish urban children: A comparison of different BMI and WHtR standards

Item Type Journal Article

Author P. Tomaszewski

Author P. Zmijewski

Author K. Milde

Author E. Sienkiewicz-Dianzenza

Abstract Background: An increase in overweight and obesity rates among children is a major social problem; however, interpretation and comparability of estimations may be affected by the reference values and cut-off points used. The aim of the study was to assess the prevalence of underweight, overweight, obesity and central obesity in 7-year-old to 10-year-old urban children and to compare the results obtained through various standards of BMI or waist-to-height ratio (WHtR) indicators. Methods: The research was conducted on a sample group of 367 girls and 424 boys aged 6.5-10.5 years, randomly chosen from a number of primary schools in Warsaw, Poland. In all participants, basic somatic features were assessed, and based on BMI and WHtR values, participants were then classified according to different standards. The prevalence of underweight, overweight, obesity and central obesity in boys and girls was compared using the chi-square test; fractions obtained from various BMI and WHtR standards were compared through a test for proportions; and the conformity of classification methods was assessed using Cohen's kappa coefficient. Results: Approximately 9 % of girls and 6 % of boys were underweight, 15 % of all participants was classified as overweight, and approximately 4 % of girls and 6 % of boys aged 7-10 were obese. Central obesity was diagnosed in 18.6-20.9 % of all participants, while another 7.1 % of girls and 7.5 % of boys displayed symptoms of excessive fat deposition characterized by elevated body fat percentages. Even though the prevalence estimations varied depending on the standards used, the overall classification compliance reached 86-94 % with a Cohen's kappa coefficient ranging from 0.676 to 0.841. Conclusion: The prevalence of underweight, overweight and obesity among urban children is comparable to estimates for the general population. Of particular concern, in terms of health and proper physical development, is the problem of central obesity that affects one out of five children. The use of reference values representing body fat percentage seems justified as it allows for a more precise diagnosis of weight-related disorders, including the particularly threatening abdominal obesity. © 2015 Tomaszewski et al.

Weighted and Class-Specific Maximum Mean Discrepancy for Unsupervised Domain Adaptation

Item Type Journal Article

Author H. Yan

Author Z. Li

Author Q. Wang

Author P. Li

Author Y. Xu

Author W. Zuo

Abstract Although maximum mean discrepancy (MMD) has achieved great success in unsupervised domain adaptation (UDA), most of existing UDA methods ignore the issue of class weight bias across domains, which is ubiquitous and evidently gives rise to the degradation of UDA performance. In this work, we propose two improved MMD metrics, i.e., weighted MMD (WMMD) and class-specific MMD (CMMD), to alleviate the adverse effect caused by the changes of class prior distributions between source and target domains. In WMMD, class-specific auxiliary weights are deployed to reweigh the source samples. In CMMD, we calculate the MMD for each class of source and target samples. Since the class labels of target samples are unknown for UDA problem, we present a classification expectation-maximization algorithm to estimate the pseudo-labels of target samples on the fly and update the model parameters using estimated labels. The proposed methods can be flexibly incorporated into deep convolutional neural networks to form WMMD and CMMD based domain adaptation networks, which we called WDAN and CDAN, respectively. By combining WMMD with CMMD, we present a CWMMD based domain adaptation network (CWDAN) to further improve classification performance. Experiments show that, both WMMD and CMMD benefit the classification accuracy, and our CWDAN can achieve compelling UDA performance in comparison with MMD and the state-of-the-art UDA methods. © 1999-2012 IEEE.

Weighted fuzzy similarity relations in case-based reasoning: A case study in classification

Item Type Conference Paper

Author S. Sandri

Author J. Mendonça

Author F. Martins-Bedê

Author R. Guimarães

Author O. Carvalho

Abstract This paper describes a fuzzy similarity relation approach to Case-Based Reasoning. Residuated implication operators are used to create a fuzzy resemblance relation between cases, modeling the CBR basic principle the more

similar the problem descriptions are, "the more similar the solution descriptions are" as a fuzzy gradual rule. We take the classification of Schistosomiasis prevalence estimation in a region of Brazil as case study, in order to investigate the effects in such a framework of weighting cases individually in classification tasks, considering a set of training strategies. © 2012 IEEE.

Weighted support vector machine for extremely imbalanced data

Item Type Journal Article

Author J. Mun

Author S. Bang

Author J. Kim

Abstract Based on an asymptotically optimal weighted support vector machine (SVM) that introduces label shift, a systematic procedure is derived for applying oversampling and weighted SVM to extremely imbalanced datasets with a cluster-structured positive class. This method formalizes three intuitions: (i) oversampling should reflect the structure of the positive class; (ii) weights should account for both the imbalance and oversampling ratios; (iii) synthetic samples should carry less weight than the original samples. The proposed method generates synthetic samples from the estimated positive class distribution using a Gaussian mixture model. To prevent

overfitting to excessive synthetic samples, different misclassification penalties are assigned to the original positive class, synthetic positive class, and negative class. The proposed method is numerically validated through simulations and an analysis of Republic of Korea Army artillery training data. © 2024 Elsevier B.V.

What Causes the Failure of Explicit to Implicit Discourse Relation Recognition?

Item Type Conference Paper
Author W. Liu
Author S. Wan
Author M. Strube
Editor Duh K.
Editor Gomez H.
Editor Bethard S.

Abstract We consider an unanswered question in the discourse processing community: why do relation classifiers trained on explicit examples (with connectives removed) perform poorly in real implicit scenarios? Prior work claimed this is due to linguistic dissimilarity between explicit and implicit examples but provided no empirical evidence. In this study, we show that one cause for such failure is a label shift after connectives are eliminated. Specifically, we find that the discourse relations expressed by some explicit instances will change when connectives disappear. Unlike previous work manually analyzing a few examples, we present empirical evidence at the corpus level to prove the existence of such shift. Then, we analyze why label shift occurs by considering factors such as the syntactic role played by connectives, ambiguity of connectives, and more. Finally, we investigate two strategies to mitigate the label shift: filtering out noisy data and joint learning with connectives. Experiments on PDTB 2.0, PDTB 3.0, and the GUM dataset demonstrate that classifiers trained with our strategies outperform strong baselines. ©2024 Association for Computational Linguistics.

Abstract Uncertainty Quantification (UQ) is essential for creating trustworthy machine learning models. Recent years have seen a steep rise in UQ methods that can flag suspicious examples, however, it is often unclear what exactly these methods identify. In this work, we propose a framework for categorizing uncertain examples flagged by UQ methods in classification tasks. We introduce the confusion density matrix-a kernel-based approximation of the misclassification density-and use this to categorize suspicious examples identified by a given uncertainty method into three classes: out-of-distribution (OOD) examples, boundary (Bnd) examples, and examples in regions of high in-distribution misclassification (IDM). Through extensive experiments, we show that our framework provides a new and distinct perspective for assessing differences between uncertainty quantification methods, thereby forming a valuable assessment benchmark. © 2023 Neural information processing systems foundation. When Invariant Representation Learning Meets Label Shift: Insufficiency and Theoretical Insights

Item Type Journal Article**Author** Y.-W. Luo**Author** C.-X. Ren

Abstract As a crucial step toward real-world learning scenarios with changing environments, dataset shift theory and invariant representation learning algorithm have been extensively studied to relax the identical distribution assumption in classical learning setting. Among the different assumptions on the essential of shifting distributions, generalized label shift (GLS) is the latest developed one which shows great potential to deal with the complex factors within the shift. In this paper, we aim to explore the limitations of current dataset shift theory and algorithm, and further provide new insights by presenting a comprehensive understanding of GLS. From theoretical aspect, two informative generalization bounds are derived, and the GLS learner are proved to be sufficiently close to optimal target model from the Bayesian perspective. The main results show the insufficiency of invariant representation learning, and prove the sufficiency and necessity of GLS correction for generalization, which provide theoretical supports and innovations for exploring generalizable model under dataset shift. From methodological aspect, we provide a unified view of existing shift correction frameworks, and propose a kernel embedding-based correction algorithm (KECA) to minimize the generalization error and achieve successful knowledge transfer. Both theoretical results and extensive experiment evaluations demonstrate the sufficiency and necessity of GLS correction for addressing dataset shift and the superiority of proposed algorithm. © 1979-2012 IEEE.

When the Personal Becomes Political: Unpacking the Dynamics of Sexual Violence and Gender Justice Discourses Across Four Social Media Platforms

Item Type Journal Article**Author** J. Suk**Author** Y. Zhang**Author** Z. Yue**Author** R. Wang**Author** X. Dong**Author** D. Yang**Author** R. Lian

Abstract We propose a three-pronged framework to study discourses surrounding social media activism initiated by networked counterpublics: personalized expressions that share stories and support, demands for changes that address systematic problems, and contentions between various actors and perspectives. Situating our analysis in discourses related to sexual violence and gender justice activism on Twitter, Facebook, Instagram, and Reddit, we use supervised machine learning to quantify three discourses—networked acknowledgment, calls to action, and feminism contention—and apply time series analysis to model their interrelations. Results show that networked acknowledgment stimulated both calls to action and feminism contention and that calls to action predicted feminism contention across all platforms.

These discourses were more sensitive to real-world events on Twitter and Facebook, but more ephemeral and cyclical on Instagram and more persistent and coupled on Reddit. Our findings speak to the opportunities and challenges in social media activism and underscore cross-platform similarities and differences. © The Author(s) 2023.

Which Uncertainty Quantification Method in Deep Learning Models for Knee Osteoarthritis Diagnosis?

Item Type Conference Paper

Author M.D. Fall

Author E.C. Faye

Abstract This article focuses on uncertainty quantification (UQ) in deep learning methods for knee osteoarthritis (OA) diagnosis. Knee OA is one of the leading causes of physical disability worldwide, with a high personal and socio-economic burden. However, the detection of knee OA relies on visual assessment, which is highly

subjective. Recently, deep learning has led to remarkable improvements in the detection of knee OA. However, the deep learning methods proposed in the current literature seem to be more concerned with model performance than with UQ. In this paper, we explore several UQ methods that aim to complement existing deep learning approaches. In particular, we consider conformal prediction, Monte Carlo dropout and evidential deep learning. The advantages and disadvantages of each method are highlighted in the context of the particular application. The aim is to provide a simple means of expressing uncertainty while allowing greater model transparency for clinical users. © 2025 IEEE.

White Blood Cells Classification Model using Automatic Soft Computing

Item Type Conference Paper

Author P.P. Mahale

Author R.K. Deshmukh

Author P. Pise

Author S.R. Rangari

Abstract Accurate classification of blood cells, especially WBCs, is crucial for disease diagnosis and management. Traditional optical microscopic imaging provides limited information, but hyperspectral imaging (combining spatial and spectral data) offers richer insights. There are challenges and opportunities in white blood cell (WBC) classification using both Convolutional Neural Networks (CNN) including the following: (1) Important data, such as representative characteristics at various frequencies and orientations, may be lost due to the CNN model's usage of local receptive fields, shared weights, and subsamples. (2) To avoid over fitting, deep neural networks need a large pool of labeled training models. and (3) the higher computational overhead is yet another challenge. Therefore, these challenges motivate us the need of the proposed study. The scope of the proposed study is limited to the classification of WBC cells. Framework to classify and count the leukocytes in microscopic images and developed framework supports the pathologist and boosts the CAD system accuracy. The process of analyzing leukocytes in microscopic blood images is the major concern of this research. In this thesis, first we work on WBCs segmentation from microscopic blood images. © 2024 IEEE.

Whole slide image representation in bone marrow cytology

Item Type Journal Article

Author Y. Mu

Author H.R. Tizhoosh

Author T. Dehkharghanian

Author C.J.V. Campbell

Abstract One of the goals of AI-based computational pathology is to generate compact representations of whole slide images (WSIs) that capture the essential information needed for diagnosis. While such approaches have been applied to histopathology, few applications have been reported in cytology. Bone marrow aspirate cytology is the basis for key clinical decisions in hematology. However, visual inspection of aspirate specimens is a tedious and complex process subject to variation in interpretation, and hematopathology expertise is scarce. The ability to generate a compact representation of an aspirate specimen may form the basis for clinical decision-support tools in hematology. In this study, we leverage our previously published end-to-end AI-based system for counting and classifying cells from bone marrow aspirate WSIs, which enables the direct use of individual cells as inputs rather than WSI patches. We then construct bags of individual cell features from each WSI, and apply multiple instance learning to extract their vector representations. To evaluate the quality of our representations, we conducted WSI retrieval and classification tasks. Our results show that we achieved a mAP@10 of 0.58 ± 0.02 in WSI-level image retrieval, surpassing the random-retrieval baseline of 0.39 ± 0.1 . Furthermore, we predicted five diagnostic labels for individual aspirate WSIs with a weighted-average F1 score of 0.57 ± 0.03 using a k-nearest-neighbors (k-NN) model, outperforming guessing using empirical class prior probabilities (0.26 ± 0.02). We present the first example of exploring trainable mechanisms to generate compact, slide-level representations in bone marrow cytology with deep learning. This method has the potential to summarize complex semantic information in WSIs toward improved diagnostics in hematology, and may eventually support AI-assisted computational pathology approaches. © 2023 The Author(s)

Whole-body tumor burden in PET/CT expert review

Item Type Journal Article

Author D.F. Santos

Author M.E. Takahashi

Author M. Camacho

Author M.C.L. de Lima

Author B.J. Amorim

Author E.M. Rohren

Author E. Etchebehere

Abstract Introduction: PET/CT whole-body tumor burden (WBTB), as a measure for overall burden of cancer, has been shown bear a strong correlation with prognosis. In the last decade, there has been significant progress in WBTB determination because of software advances and the increasing availability of positron-emitting radiopharmaceuticals. However, the determination of tumor burden with PET/CT is still a challenge especially in widespread metastatic disease. Methods: In this non-systematic review, we will discuss the current role of determination of WBTB in cancer such as non-small cell lung cancer, lymphoma, breast cancer, among others and with a variety of radiotracers. Furthermore, we will address imaging techniques and quantification methods available and challenges. Results: Many types of segmentation methods and different thresholds according to tumor types and radiotracers can be applied. These variations may show different WBTB results, but in general, despite variations, WBTB determination for staging purposes in lung cancer, breast cancer, lymphoma, melanoma, prostate cancer and neuroendocrine tumors have shown to bear a strong correlation with patient prognosis. Conclusion: PET/CT whole-body tumor burden has an invaluable potential to assess prognosis. The accelerated radiopharmaceutical development will provide molecules and

mechanisms to determine WBTB with advanced imaging qualification tools to further adjust radiotherapeutic doses in oncology. WBTB will most likely only become routinely accessible in clinical practice when fully automated programs become available and standardized. © 2022, The Author(s), under exclusive licence to Italian Association of Nuclear Medicine and Molecular Imaging.

Why and how post-mastectomy edema should be quantified in patients with breast cancer

Item Type Journal Article

Author C. Galland

Author J.F. Auvert

Author A. Flahault

Author M. Vayssairat

Abstract In the present study, we advocate quantifying post-mastectomy edema in patients with breast cancer in millilitres and not in centimetre, contrarily to the usual routine practice. The water displacement and perimetric quantification methods exhibited both excellent reproducibility with an intraclass correlation coefficient > 0.99 and an accuracy coefficient $< 0.3\%$.

Why do we think? The dynamics of spontaneous thought reveal its functions

Item Type Journal Article

Author J.N. Mildner

Author D.I. Tamir

Abstract Spontaneous thought—mind wandering, daydreaming, and creative ideation—makes up most of everyday cognition. Is this idle thought, or does it serve an adaptive function? We test two hypotheses about the functions of spontaneous thought: First, spontaneous thought improves memory efficiency. Under this hypothesis, spontaneous thought should prioritize detailed, vivid episodic simulations. Second, spontaneous thought helps us achieve our goals. Under this hypothesis, spontaneous thought should prioritize content relevant to ongoing goal pursuits, or current concerns. We use natural language processing and machine learning to quantify the dynamics of thought in a large sample ($N = 3,359$) of think aloud data. Results suggest that spontaneous thought both supports memory optimization and keeps us focused on current concerns. © The Author(s) 2024.

Why Engineers Should Not Attempt to Quantify GSI

Item Type Journal Article

Author B. Yang

Author D. Elmo

Abstract In the past decade, there has been an increasing trend of digitalizing rock engineering processes. However, this process has not been accompanied by a critical analysis of the very same empirical methods that many complex numerical and digital methods

are founded upon. As engineers, we are taught to use and trust numbers. Indeed, we would not be able to define the factor of the safety of a structure without numbers. However, what happens when those numbers are nothing but numerical descriptions of qualitative assessments? In this paper we present a critical review of the many attempts presented in the literature to quantify GSI (geological strength index). To the authors' knowledge, this paper represents the first time that all the different GSI tables and quantification methods that have been proposed over the past two decades are collated and compared critically. In our critique, we argue against the paradigm whereby the quantification process adds the experience factor for inexperienced engineers. Furthermore, we discuss the limitations of the notion that GSI quantification methods could transform subjectivity into objectivity since the parameters under considerations are not quantitative measurements. Relying on empirically defined quantitative equivalences raises important questions, particularly when these quantitative equivalences are being used to define so-called accurate rock mass classification input for design purposes. © 2022 by the authors.

Why is quantification an interesting learning problem?

Item Type Journal Article

Author P. González

Author J. Díez

Author N. Chawla

Author J.J. del Coz

Abstract There are real applications that do not demand to classify or to make predictions about individual objects, but to estimate some magnitude about a group of them. For instance, one of these cases happens in sentiment analysis and opinion mining. Some applications require to classify opinions as positives or negatives, but there are also others, even more useful sometimes, that just need an estimation of which is the proportion of each class during a concrete period of time. “How many tweets about our new product were positive yesterday?” Practitioners should apply quantification algorithms to tackle this kind of problems, instead of just using off-the-shelf classification methods, because classifiers are suboptimal in the context of quantification tasks. Unfortunately, quantification learning is still relatively an under explored area in machine learning. The goal of this paper is to show that quantification learning is an interesting open problem. To support its benefits, we shall show an application to analyze Twitter comments in which even the most simple quantification methods outperform classification approaches. © 2016, Springer-Verlag Berlin Heidelberg.

Wilson disease in the USA: epidemiology and real-world patient characteristics based on a retrospective observational health claims study

Item Type Journal Article

Author S. Fang

Author C. Strader

Author H. Costantino

Author K.H. Weiss

Author P. Hedera

Abstract Objectives To describe the epidemiology, patient characteristics and comorbidities in patients with Wilson disease (WD) in the USA. Design Retrospective, population-based study. Setting The study used the US Komodo claims database containing records regarding medical claims for over 120 million individuals. Participants Patients with WD were identified via ICD-10 (10th revision of the International Classification of Diseases) code during the study period 2016-2019 and no age restriction was applied. A further stratification by disease subtype ('hepatic', 'neurologic' and 'psychiatric') was performed. Main outcome measures WD prevalence was reported by age, sex and US census regions/divisions. Adjusted prevalence was calculated using age-specific prevalence standardised to the USA (2010 US census) and to the world (WHO 2000-2025) to enable comparisons across countries, using direct standardisation of prevalence estimates by age group. Results Overall, 2115 patients with WD were identified during the study period. Among them, 56.8% had hepatic symptoms, 57.0% neurologic symptoms and 47.4% psychiatric symptoms. The most frequent manifestations in hepatic patients were liver signs and symptoms (90.8%), in neurologic patients cognitive defects (50.7%) and in psychiatric patients mood disorders (86.4%). The mean age in the overall cohort was 39.9 years. Prevalence estimation was based on 1481 patients with WD between 2017 and 2019. The 2017-2019 crude period prevalence was 21.2 patients per million (95% CI: 20.1 to 22.3), with similar prevalence observed for both sexes. Conclusions This study provides important real-world data on the diagnosed prevalence of WD in the USA and revealed the comorbidities associated with various disease subtypes, thereby providing a comprehensive basis for guiding physicians and policy makers in the management of this chronic disease. © Author(s) (or their employer(s)) 2024. WOT-Class: Weakly Supervised Open-world Text Classification

Item Type Conference Paper

Author T. Wang

Author Z. Wang

Author W. Liu

Author J. Shang

Abstract State-of-the-art weakly supervised text classification methods, while significantly reduced the required human supervision, still requires the supervision to cover all the classes of interest. This is never easy to meet in practice when humans explore new, large corpora without complete pictures. In this paper, we work on a novel yet important problem of weakly supervised open-world text classification, where supervision is only needed for a few examples from a few known classes and the machine should handle both known and unknown classes in test time. General open-world classification has been studied mostly using image classification; however, existing methods typically assume the availability of sufficient known-class supervision and strong unknown-class prior knowledge (e.g., the number and/or data distribution). We propose a novel framework WOT-Class that lifts those strong assumptions. Specifically, it follows an iterative process of (a) clustering text to new classes, (b) mining and ranking indicative words for each class, and (c) merging redundant classes by using the overlapped indicative words as a bridge. Extensive experiments on 7 popular text

classification datasets demonstrate that WOT-Class outperforms strong baselines consistently with a large margin, attaining 23.33% greater average absolute macro-F1 over existing approaches across all datasets. Such competent accuracy illuminates the practical potential of further reducing human effort for text classification. © 2023 Copyright held by the owner/author(s).

WOUND MANAGEMENT, HEALING, AND EARLY PROSTHETIC REHABILITATION: PART 3 - A SCOPING REVIEW OF CHEMICAL BIOMARKERS

Item Type Journal Article

Author H. Williams-Reid

Author A. Johannesson

Author A.A. Buis

Abstract **BACKGROUND:** Poor post-amputation healing delays prosthetic fitting, adversely affecting mortality, quality of life, and cardiovascular health. Current residual limb assessments are subjective and lack standardized guidelines, emphasizing the need for objective biomarkers to improve healing and prosthesis readiness assessments. **OBJECTIVE(S):** This review aimed to identify predictive, diagnostic, and indicative chemical biomarkers of healing of the tissues and structures found in the residual limbs of adults with amputation. **METHODOLOGY:** This scoping review followed Joanna Briggs Institute (JBI) and PRISMA-ScR guidelines. Searches using the terms “biomarkers,” “wound healing,” and “amputation” were performed across Web of Science, Ovid Medline, Ovid Embase, Scopus, Cochrane, PubMed, and CINAHL databases. Inclusion criteria were: 1) References to chemical biomarkers and healing; 2) Residuum tissue healing; 3) Repeatable methodology with ethical approval. Included articles were evaluated for quality of evidence (QualSyst tool) and level of evidence (JBI classification). Sources were categorized by study (e.g., randomized controlled trial or bench research), wound (diabetic, amputation, other), and model (human, murine, other) type. Chemical biomarkers repeated across study categories, and quantification methods were reported on. **FINDINGS:** From 3,306 titles and abstracts screened, 646 underwent full-text review, and 203 met the criteria for data extraction, with 76% classified as strong quality. 38 chemical biomarkers were identified across 4 to 50 sources, with interleukins (predictive, indicative, and diagnostic) and HbA1c (predictive) most prevalent, appearing in 50 and 48 sources, respectively. Other biomarkers included predictive blood markers (e.g., cholesterol, white blood cell counts), indicative growth factors, bacteria presence (predictive), proteins (predictive, indicative, and diagnostic, e.g., matrix metalloproteinases), and cellular markers (indicative and diagnostic, e.g., Ki-67, alpha-smooth muscle actin [α -SMA]). **CONCLUSION:** Predictive biomarkers identify comorbidities that may hinder healing, aiding in pre-amputation risk assessment for poor recovery. Indicative biomarkers monitor key biological healing processes, such as angiogenesis (the formation of new blood vessels), wound contraction, and inflammation. Diagnostic biomarkers provide direct insights into tissue composition and cellular-level healing. Integrating these biomarkers into post-amputation assessments enables continuous monitoring of the healing process while accounting for comorbidities, enhancing the objectivity of post-surgical healing management and ensuring more effective, personalized rehabilitation strategies. © 2025 Canadian Online Publication Group. Wrapper positive Bayesian network classifiers

Item Type Journal Article

Author B. Calvo

Author I. Inza

Author P. Larrañaga

Author J.A. Lozano

Abstract In the information retrieval framework, there are problems where the goal is to recover objects of a particular class from big sets of unlabelled objects. In some of these problems, only examples from the class we want to recover are available. For such problems, the machine learning community has developed algorithms that are able to learn binary classifiers in the absence of negative examples. Among them, we can find the positive Bayesian network classifiers, algorithms that induce Bayesian network classifiers from positive and unlabelled examples. The main drawback of these algorithms is that they require some previous knowledge about the a priori probability distribution of the class. In this paper, we propose a wrapper approach to tackle the learning when no such information is available, setting this probability at the optimal value in terms of the recovery of positive examples. The evaluation of classifiers in positive unlabelled learning problems is a non-trivial question. We have also worked on this problem, and we have proposed a new guiding metric to be used in the search for the optimal a priori probability of the positive class that we have called the pseudo F. We have empirically tested the proposed metric and the wrapper classifiers on both synthetic and real-life datasets. The results obtained in this empirical comparison show that the wrapper Bayesian network classifiers provide competitive results, particularly when the actual a priori probability of the positive class is high. © 2012 Springer-Verlag London Limited.

Yield gap and resource utilization efficiency of three major food crops in the world – A review

Item Type Journal Article

Author L.-B. RONG

Author K.-Y. GONG

Author F.-Y. DUAN

Author S.-K. LI

Author M. ZHAO

Author J. HE

Author W.-B. ZHOU

Author Q. YU

Abstract Yield gap analysis could provide management suggestions to increase crop yields, while the understandings of resource utilization efficiency could help judge the rationality of the management. Based on more than 110 published papers and data from Food and Agriculture Organization (FAO, www.fao.org/faostat) and the Global Yield Gap and Water Productivity Atlas (www.yieldgap.org), this study summarized the concept, quantitative method of yield gap, yield-limiting factors, and resource utilization efficiency of the three major food crops (wheat, maize and rice). Currently, global potential yields of wheat, maize and rice were 7.7, 10.4 and 8.5 t ha⁻¹,

respectively. However, actual yields of wheat, maize and rice were just 4.1, 5.5 and 4.0 t ha⁻¹, respectively. Climate, nutrients, moisture, crop varieties, planting dates, and socioeconomic conditions are the most mentioned yield-limiting factors. In terms of resource utilization, nitrogen utilization, water utilization, and radiation utilization efficiencies are still not optimal, and this review has summarized the main improvement measures. The current research focuses on quantitative potential yield and yield gap, with a rough explanation of yield-limiting factors. Subsequent research should use remote sensing data to improve the accuracy of the regional scale and use machine learning to quantify the role of yield-limiting factors in yield gaps and the impact of change crop management on resource utilization efficiency, so as to propose reasonable and effective measures to close yield gaps. © 2021 CAAS. Zono-Conformal Prediction: Zonotope-Based Uncertainty Quantification for Regression and Classification Tasks

Item Type Journal Article

Author L. Lützow

Author M. Eichelbeck

Author M.J. Kochenderfer

Author M. Althoff

Abstract Conformal prediction is a popular uncertainty quantification method that augments a base predictor to return sets of predictions with statistically valid coverage guarantees. However, current methods are often computationally expensive and data-intensive, as they require constructing an uncertainty model before calibration. Moreover, existing approaches typically represent the prediction sets with intervals, which limits their ability to capture dependencies in multi-dimensional outputs. We address these limitations by introducing zono-conformal prediction, a novel approach inspired by interval predictor models and reachset-conformant identification that constructs prediction zonotopes with assured coverage. By placing zonotopic uncertainty sets directly into the model of the base predictor, zono-conformal predictors can be identified via a single, data-efficient linear program. While we can apply zono-conformal prediction to arbitrary nonlinear base predictors, we focus on feed-forward neural networks in this work. Aside from regression tasks, we also construct optimal zono-conformal predictors in classification settings where the output of an uncertain predictor is a set of possible classes. We provide probabilistic coverage guarantees and present methods for detecting outliers in the identification data. In extensive numerical experiments, we show that zono-conformal predictors are less conservative than interval predictor models and standard conformal prediction methods, while achieving a similar coverage over the test data. © 2025 Laura Lützow, Michael Eichelbeck, Mykel J.
